AMBULANCE ELECTRICAL SYSTEM STUDY. FINAL REPORT

A study was conducted to develop recommendations for a revision of the Federal Ambulance Specifications (KKK-A-1822), the overall goal being to determine the electrical needs of the modern ambulance and to develop a model system which is economical and energy-efficient, safe for the patient and operator, which allows future growth, and provides the maximum in reliability and maintainability. It was found that the ambulance electrical system is almost always overloaded. Options for increasing generating capacity are described (a dual alternator, and an apparatus to increase an automotive alternator's output by increasing the generated voltage). It is recommended that the balance between load demand and generating capacity be improved, a reduction in load being the preferred option. Although most electrical system configurations encountered were satisfactory, a preferred configuration is described (paralleled batteries, a manual battery selector switch, a diode isolator, and an ammeter and voltmeter). Since most electrical system faults are due to poor manufacturer quality control, it is recommended that quality control be institutionalized by the ambulance manufacturer's trade organization. Electrical load management is recommended to ambulance operators. It is shown that a harmful shock from a nominal 12 VDC (volts, direct current) source is not possible. With 110 VAC, (volts, alternating current) macroshock is possible for both patient and attendant personnel. A 110 VAC source is not needed on most ambulances. The static inverter is not recommended as a required ambulance item. A somewhat tutorial discussion is presented on nickel-cadmium and sealed lead-acid battery characteristics, including their significance to ambulance personnel. It is generally recommended that ambulance personnel follow manufacturer's recommendations. Some general guidelines on battery use are presented as well as recommended procedures in lieu of manufacturer's instructions.

STUDY OF THE EFFECTS OF APPLYING FEDERAL MOTOR VEHICLE SAFETY STANDARD 201 TO LIGHT TRUCKS AND VANS. FINAL REPORT

From a careful inspection of specimen trucks, their possible compliance or noncompliance with the requirements of Federal Motor Vehicle Safety Standard (FMVSS) 201, Occupant Protection in Interior Impact--Passenger Cars, was determined. Where noncompliance was indicated, design studies were made to bring the trucks into compliance. The added weight of the new designs was estimated, as well as the cost of the new design features (manufacturing, wholesale, dealer markup, and total consumer costs). After the average service life was established for each light truck and van make and model, a lifetime fuel operating cost was estimated. The impact on production leadtime was analyzed. Based on 1978 production volumes, the estimated average cost per truck of complying with FMVSS 201 requirements would be $4.43.

STUDY OF THE EFFECTS OF APPLYING FEDERAL MOTOR VEHICLE SAFETY STANDARDS 203 AND 204 TO LIGHT TRUCKS AND VANS. FINAL REPORT

From a careful inspection of specimen trucks, their possible compliance or noncompliance with the requirements of Federal Motor Vehicle Safety Standard (FMVSS) 203, Impact Protection for the Driver from the Steering Control System--Passenger Cars, and FMVSS 204, Steering Control Rearward Displacement--Passenger Cars, was determined. Where noncompliance was indicated, design studies were made to bring the trucks into compliance. The added weight of the new designs was estimated, as well as the cost of the new design features (manufacturing, wholesale, dealer markup, and total consumer costs). The average service life of each light truck and van make and model was established. The impact on production leadtime was analyzed. Based on 1978 production volumes, the average cost per truck of complying with FMVSS'S 203 and 204 would be $11.35.

COST EVALUATION FOR FOUR FEDERAL MOTOR VEHICLE STANDARDS. TASK 7: COST REVIEW OF PEDESTRIAN SAFETY MODIFICATIONS. FINAL REPORT

Minor changes have been proposed in a 1978 Pontiac LeMans front bumper system modified by Battelle Labs. (Columbus, Ohio) to improve pedestrian impact protection. Generally, resilient plastic foam was substituted for the rigid steel bumper components. The minor changes proposed in the prototype configuration are for improved production possibilities. A cost estimate has been made of the original production design and the revised prototype. A 12-lb weight saving and a $5.71 increase in consumer cost were found.

DEVELOPMENT OF A TEST METHODOLOGY FOR EVALUATING CRASH COMPATIBILITIES AND AGGRESSIVENESS. VOL. 2: TECHNICAL REPORT. FINAL REPORT

A program to establish a test methodology for evaluating crash compatibility and aggressiveness of intermediate, subcompact, and lightweight subcompact cars is described. As a result of this program, the NHTSA (National Hwy. Traffic Safety Administration) Test Device was developed to measure the basic types of aggressiveness (architectural, mass, and structural). This Test Device is a unique, segmented, honeycomb, load-measuring tool which is adaptable to both moving-and fixed-barrier collisions. Eight full-scale, car-to-Test Device collisions were conducted to provide comprehensive data comparisons between moving and fixed barrier tests. The four representative 1975 models used were the Honda Civic CVCC, Volvo 244DL, Ford Torino, and Plymouth Fury. Data comparisons were also made with results of previously conducted car-to-car and car-to-fixed barrier tests. Vehicle aggressivity assessment is addressed, illustrating some simple approaches for determining the relative aggressivity of two vehicles, using the Ford Torino and Plymouth Fury as examples. Possible methodologies for assessing a vehicle's compatibility with a selected traffic scenario are also addressed. Conclusions and recommendations are presented, based on the data from the eight car-to-car tests, including recommendations for improving the design and load-measuring capability of the NHTSA Test Device and for using it in future research.

DEVELOPMENT OF A TEST METHODOLOGY FOR EVALUATING CRASH COMPATIBILITY AND AGGRESSIVENESS. TEST REPORT 2, 1975 FORD TORINO-TO-NHTSA TEST DEVICE. FINAL REPORT

Results are presented of two full-scale, head-on collisions between the NHTSA (National Hwy. Traffic Safety Administration) Test Device and 1975 Ford Torino four-door sedans. These are Tests No. 3 and No. 4 of a series of eight tests to help establish a test methodology for evaluating crash compatibility and aggressiveness. The NHTSA Test Device is a unique, honeycomb-faced, load-measuring tool adaptable to both moving- and fixed-barrier collisions. Data presented include graphical and tabular presentations of vehicle deformation; Test Device load cell data; vehicle and simulated occupant acceleration, velocity, and displacement values; dynamic displacement of string potentiometers, and restraint survival distances. Also included are tabular summaries of occupant injury criteria, exterior and interior static vehicle deformation, and restraint system loads and vehicle descriptions. Data for a 40-mph fixed Test Device collision are compared to those for an "equivalent" moving Test Device collision.

ENFORCEMENT OF THE NATIONAL MAXIMUM SPEED LIMIT. ENFORCEMENT PRACTICES AND PROCEDURES. FINAL TECHNICAL REPORT

In this first phase of a three-phase project concerned wi
national maximum speed limit (NMSL) enforcement procedur
work was undertaken to develop a profile of existing practic
techniques, and procedures used by state police and highw
patrols to enforce the NMSL. A resource document was dev
oped and distributed to the state law enforcement agencies
obtain data on personnel and equipment resources of t
agency, agency responsibilities, and procedures or patrol co
figurations by which the agency enforces the NMSL, as well
influences outside the agency which affect NMSL enforceme
Responses to the resource document (a copy of which is
pended) form the basis of this state-of-the-art report. Based
the responses, ten states were selected and visited for the p
pose of data verification and a closer examination of NM
enforcement in the field. Observations are provided on the
forcement practices of Arizona, Arkansas, California, Colora
Georgia, Iowa, Maryland, Massachusetts, New York, and Oh
The conclusion of the overall study is that state law enfor

ment agencies are enforcing the NMSL vigorously, considering available resources. Enforcement actions are taken by nearly all officers in nearly all jurisdictions when violator speeds reach 65 or 66 mph. Unusually high speed violations are rare. The majority of the public is accepting the NMSL. The respondents favored the single officer patrol unit with radar, although team configurations are very effective. Some reasonable proportion of enforcement units should be unmarked camouflaged vehicles, or aircraft, to combat the widespread use of Citizens Band radios by motorists. All on-duty units should be equipped with moving radar units. The stopwatch, the least expensive speed detection device, should supplement speedometer and radar on surface units.

THE EARLYRIDER SHOPPING GUIDE TO INFANT/CHILD AUTOMOBILE RESTRAINTS

As of Feb 1979, this is a complete listing of those infant and child restraints currently in production which have been determined to perform satisfactorily in dynamic tests according to the requirements of the 1978 proposed revision to Federal Motor Vehicle Safety Standard 213. The listing is divided into three major categories: restraints for infants only (from birth to 20 lb), convertible restraints for infants and toddlers, and restraints for toddlers only (from the time they can sit alone until they weigh 40 lb or 50 lb). Information is given on the reasons for infant and child restraint use, the selection of the most suitable restraint, and the proper use of restraints. Illustrations are provided of the different restraint models.

MULTILEVEL STUDY OF ACCIDENT CAUSATION AND AVOIDANCE: PHASE 1A PLANNING REPORT. INTERIM REPORT

Planning phase efforts are described in the selection of a methodology for conducting a multilevel study of accident causation and avoidance. The steps required to achieve this goal were definition and development of an accident-causation model, identification of research topics for further study, and development of experimental projects for studying the selected factors. A review of highway-related literature showed that the case study approach has been the basis of most previous accident-causation research. The medical literature suggested an alternative in the statistical inference approach, a probabilistic model. The characteristics of the two approaches are described and the probabilistic model is recommended for the Phases 2 and 3 research. This approach can deal with complex, interactive phenomena by isolating the influence of particular factors and is compatible with the National Accident Sampling System. It is recommended that the statistical inference approach be formulated in terms of multidimensional contingency tables. Three sampling techniques, commonly used in epidemiology, that give rise to contigency tables, are reviewed. Experimental projects are described for the following three research topics: accident experience in stolen vehicles (illustrating cross-sectional sampling), comparative accident experience of field-dependent drivers (prospective sampling), and comparison of tire characteristics (vehicle stability studies) in the accident and non-accident populations (retrospective sampling). Appended are a bibliography (with annotations or author abstracts), a report on the traffic conflicts technique (and its applicability to accident-causation research), and a review of the concept of induced exposure.

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 1. FINAL REPORT

The results and conclusions are summarized of a study to determine whether there are feasible and desirable activities that state agencies may perform to improve the effectiveness of motor vehicle safety defect recall campaigns. Background information is provided on the recall program and on the study itself. Results are summarized of feasibility and desirability analyses for the five most promising state activities, and a comparative evaluation is provided. The five activities include verifying compliance with safety defect recall campaigns during state safety inspections; issuance by state motor vehicle departments of follow-up recall notices; requiring franchised dealers or manufacturers to certify the compliance of all vehicles under recall when the vehicles are brought in for service or taken into inventory; production and distribution of "tearsheets" describing motor vehicle recall campaigns; and suspending registrations of recall vehicles that have not been inspected for detects and corrected, if necessary. Each of the activities was analyzed on the basis of technical, operational, and administrative feasibility; legal feasibility; political feasibility; cost; impact on campaign completion rates; and cost effectiveness. It is concluded that the five activities provide state and National Hwy. Traffic Safety Administration decision-makers with a variety of flexible, relatively inexpensive, and effective mechanisms for increasing the completion rates of motor vehicle recall campaigns.

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 2. FINAL REPORT

A detailed description and results of an analysis are provided of one potential state activity to improve the effectiveness of motor vehicle safety defect recall campaigns: verifying compliance with safety defect recall campaigns during state safety inspections. The feasibility of this activity was analyzed in terms of technical, operational, and administrative feasibility; legal feasibility; political feasibility; impact on campaign completion rates; cost; and cost effectiveness. It is concluded that the activity is technically, operationally and administratively feasible in most PMVI (periodic motor vehicle inspection) states. Legal and political feasibility vary among states, but it appears that the activity is viable in some states. The activity is highly effective in increasing campaign completion rates at low state cost and moderate total cost. Implementation as a demonstration project in an interested state is justified. The activity is especially desirable for PMVI states in which the primary objective is to effect maximum completion rates for critical recall campaigns. During a demonstration project, the following issues should be monitored and resolved: extent to which private inspection stations neglect to verify recall compliance and impact of this on activity effectiveness; impact of activity on vehicle owner attitudes toward the recall program and on completion rates of nondesignated campaigns; level of public and political support generated; and impact on vehicle service and inspection industry (especially, possible shift from nonfranchised inspection facilities to franchised dealers).

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 3. FINAL REPORT

A detailed description and results of an analysis are provided of one potential state activity to improve the effectiveness of motor vehicle safety defect recall campaigns: issuance by state motor vehicle departments of follow-up recall notices. The feasibility of this activity was analyzed in terms of technical, operational, and administrative feasibility; legal feasibility; political feasibility; impact on campaign completion rates; cost; and cost effectiveness. It is concluded that the activity is technically, operationally, and administratively feasible in most states. State issuance of follow-up recall notices is likely to be legally and politically viable in many states. The activity would effect small to moderate increases in campaign completion rates at relatively low cost. Implementation of this activity as a demonstration project in one or more states is justified. The activity is especially desirable in states with excess data processing capacity and in-house printing and mailing capabilities. During a demonstration project, the following issues should be explored: impact on owner response of different approaches to designing and drafting recall notices, and practicability and cost effectiveness of coordinating state follow-up notices with manufacturer and dealer follow-up activities.

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 4. FINAL REPORT

Background information is given on the National Hwy. Traffic Safety Administration (NHTSA) motor vehicle safety defect recall campaigns and on the present study to determine activites that state agencies may perform to improve recall campaign effectiveness. Comprehensive documentation is provided of recall program activities under the following headings: overview; NHTSA operations prior to beginning of a recall campaign; manufacturer defect determination process; initial recall campaign operations (manufacturer preparation and notification of NHTSA, vehicle owners, and dealers); R. L. Polk operations (a company which maintains files of state vehicle registration data to aid manufacturers in recall campaigns); vehicle inspection/correction and follow-up notification for uncorrected vehicles; and campaign monitoring and evaluation. Relevant programs operated by state agencies are described generally in the following section: overview, vehicle registration and titling programs, vehicle inspection programs, motor vehicle department data processing systems, and state agencies (other than motor vehicle departments) that may assist in recall campaigns. Topics in the discussion of state activities in recall campaigns include overview (recall program operation problems, state participation in recall program, preliminary assessment of potential state activities); key problems associated with current recall program operations; and potential state solutions to recall program problems. Appended are agenda employed to conduct interviews with state agency officials; reports generated from state visits in California, Florida, Massachusetts, New York, and Utah; a list of organizations and individuals contacted; and an annotated bibliography of background material.

IDENTIFICATION OF APPROACHES FOR THE CONTROL OF HEALTH, ENVIRONMENTAL, AND SAFETY HAZARDS ASSOCIATED WITH AIR BAG USE AND DISPOSAL. FINAL REPORT

Previous work conducted by individual automobile manufacturers, the Motor Vehicle Manufacturers Assoc., the National Hwy. Traffic Safety Administration, and other parties was examined to assess the magnitude of any potential risks associated with the use of air bag restraint systems. Specific potential hazards associated with the handling and disposal of inflator modules were identified, based on consideration of physical, biological, and human environmental impact. Individual amelioration techniques were examined for the various stages of the vehicle life cycle. A countermeasure analysis indicated that undeployed air bags in retired cars should be safely deployed early in the automobile recycling process. This deployment could take place at dismantler/recycler and scrapyard facilities, or at designated inspection-deployment centers. Ten modifications were identified that could be incorporated into inflator or air bag system designs to aid in deployment. The modifications, identified according to the signal source or device used to deploy the inflator module and ranked according to attractiveness, are as follows: 12-volt DC battery, piezoelectric igniter, electronic keyhole-less lock, self-ignition match pyrophoric added to the pyrotechnic material in the inflator, induction coil, ultraviolet radiation, radio frequency tuned squib, pulsed or continuous laser, microwave radiation, ultrasonic, and collapsible partition. The individual merits of these alternatives should be examined in more detail.

TRUCK, BUS, AND MOTORCYCLE SAFETY STATUS METHODOLOGY. VOL. 2: TECHNICAL REPORT. FINAL REPORT

A project was undertaken to determine the feasibility of surveying the safety status of the truck-, bus-, and motorcycle-in-use populations (in support of the National Hwy. Traffic Safety Administration's Vehicles-In-Use Prog.), and to develop and validate a cost-effective methodology for surveying the condition of trucks, buses, and motorcycles. Phase 1 of the project established the feasibility of such surveys. Methods for inspecting each vehicle type, and data collection strategies were designed. Representatives of affected industries and owner groups were consulted to assess the feasibility of the inspection techniques and to arrive at an optimum strategy. (Details concerning the literature review, industry consultations, and other phase 1 activities were presented in an Interim Report. Summaries of these activities are included herein.) The emphasis of this report is on the detailed survey methodology developed in Phase 2. The approach adopted involves the use of a mobile inspection team to conduct inspections at six major sites representing three types of vehicle inspection programs. Inspection procedures and methods were developed and tested using time and motion studies, and validated in actual field tests. Equipment necessary to conduct inspections was identified.

ENERGY CONSERVATION POTENTIAL OF LAND-BASED RECREATIONAL MOTOR VEHICLES. FINAL REPORT

An assessment was made of the energy conservation potential of land-based recreational vehicles (RV'S) in partial fulfillment of the requirements of the 1978 Amendment to the National Energy Policy Act which mandated the Secretary of Transportation to conduct a study of the energy conservation potential of RV'S, including aircraft, motorboats, and land-based vehicles. The present analysis involved motor homes, truck campers, motorcycles, snowmobiles, golf cars, and all-terrain vehicles. Based on personal interviews and secondary data sources, it was determined that the RV population studied was about 5 million in 1978 and may increase to 6 million in 1985. Current annual fuel consumption is about 1.4 billion gallons, slightly more than 1% of total highway fuel usage. Assuming a fuel efficiency improvement between 10% and 25%, annual savings would range between 150 and 375 million gal. or between 1-1/2% and 3% of the savings expected from passenger cars and light trucks.

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, JANUARY 1, 1979 TO DECEMBER 31, 1979

Data are tabulated for motor vehicles, equipment, and tires involved in 1979 safety related recall campaigns. For each item, the make/model, model year, number of items recalled, and a brief description of the defect are recorded. Vehicles include passenger cars, station wagons, vans (camper and travel), mini-motorhomes, motorhomes, van coaches, jeeps, four-wheel-drive vehicles, trucks (light, medium, and heavy), trailers, semi-trailers logging/pulp, tank), drill rigs, buses, school buses, transit coaches, motorcycles, mopeds, postal delivery trucks, police vehicles, and fire apparatus trucks. Equipment includes hydraulic winches (wreckers), jacks, wheels, anti-lock systems, fuel filters, camper doors and refrigerators, air conditioners, shoulder belts, frame members, axles, power steering components, luggage racks (motorcycle), telescopic hoists (trucks), brake master cylinders, fuel hose, and tires. Status of recall campaigns is given as of 30 Sep 1979.

NATIONAL ACCIDENT SAMPLING SYSTEM. SAMPLE DESIGN, PHASES 2 AND 3. VOL 1: FINAL TECHNICAL REPORT

The Phase 2 and 3 sample design for the National Accident Sampling System (NASS) recommends a procedure for the first-stage selection of Primary Sampling Units (PSU'S) and the second-stage design for the selection of accidents for investigation. Cost models are developed to estimate the operating characteristics of the NASS. The design features extensive use of stratification and clustering. Controlled probability selection is used to insure geographic dispersion of the 75 recommended investigation sites, including the initial 10 NASS pilot sites. Two types of estimation methods were proposed, unbiased inflation estimators and ratio estimators (several types). The use of balanced half-sample replications is recommended for estimating sampling errors.

INJURY CODING MANUAL 1980. FINAL REPORT

A medically accurate, concise, and practical handbook is provided for use by vehicle crash investigators in coding injury data. This manual incorporates all 1980 revisions to the Abbreviated Injury Scale (AIS) and provides a glossary of commonly used medical terms and symbols, anatomical outlines and charts, and National Accident Sampling System (NASS) coding conventions. Included are a brief history of standardized injury reporting systems; a description of the format and usage of the AIS; and the AIS injury scaling dictionary.

CALSPAN CHRYSLER RESEARCH SAFETY VEHICLE PHASE 3 FINAL DESIGN REPORT. VOL. 2: APPENDICES

The supporting documents for the final design of the Calspan
Chrysler Research Safety Vehicle (RSV) are presented. Incluc
ed are illustrations of body and chassis components; specific
tions for the RSV engine family; results of the RSV Mule C
service brake and parking brake systems tests, and of temper
ture tests; a summary of the RSV drag coefficient; and a bill
materials for the final RSV design.

A REPORT TO THE CONGRESS ON THE EFFECT OF MOTORCYCLE HELMET USE LAW REPEAL-- CASE FOR HELMET USE

An overview of the ramifications of helmet law repeal is p
sented. A brief history of the Highway Safety Acts and th
effect upon helmet laws is given. Also provided are tables a
graphs representing motorcycle fatalities per 10,000 register
vehicles. Helmet use issues are discussed, including the questio
of helmet effectiveness, the helmet's contribution to neck in
ries, and the helmet's alleged impairment of the driver's heari
and vision. Despite rapid increases in vehicle registration
tween 1958 and 1979, helmets are shown to have helped
reduce fatalities from 15 per 10,000 in 1959 to 6.4 per 10,000
1976. Post-repeal studies were contracted by the NHTSA
Kansas, Colorado, Oklahoma, and South Dakota to measure
effect of helmet laws. Specific data indicate a nearly 50% red
tion in voluntary helmet use in these states since repeal; h
injuries have increased two to three times in frequency and f
times in severity. An analysis of the additional medical c
resulting from helmet law repeal indicates increases of milli
of dollars annually for direct hospitalization and physician c
These costs are largely unpaid by the injured party and must
absorbed by society as a whole. Since the repeal or weaken
of helmet laws in 27 states in 1976, motorcycle fatalities h
increased 46% while registrations have increased only 1%. D
cussion of methods to increase voluntary use indicates a lack
knowledge of the mechanisms necessary to change rider
tudes. Congressional legislation is recommended to define
responsibilities of the states in enacting helmet use legislati

EFFECTS OF FUTURE CONDITIONS UPON MOTOR VEHICLE SAFETY REQUIREMENTS. FINAL REPORT

Near-term and exploratory rulemaking activities described in NHTSA'S "5-Year Plan for Motor Vehicle Safety Rulemaking" (published April 1979) are studied. Accidents and conditions in which the various standards can have effects are identified. Changes in the relative frequencies of the accident types and conditions are projected to the year 2000 on the basis of projections of the population, of highway use, and of the vehicle fleet. Changes between 1977 and 2000 in the proportion of traffic deaths affected by the various standards are discussed. Appended are an analysis of highway use trends, population projections for persons and vehicles, an analysis of delta V (change in velocity), taxonomies of fatalities in 1977, and summaries of side impact and truck rear underride information.

CALSPAN/CHRYSLER RESEARCH SAFETY VEHICLE. PHASE 3 FINAL TECHNICAL REPORT. VOL. 2: TECHNICAL DISCUSSION

Using a combination of mathematical modeling on the computer with static and dynamic testing, design issues that remained at the completion of Phase 2 were resolved, validation tests were conducted to demonstrate performance resulting from these design improvements, and the results incorporated in the final design. Additional investigations defined emissions and fuel economy, documented the degree of research safety vehicle (RSV) compliance with current Federal Motor Vehicle Standards, and studied the effect of the RSV design on collision repair, producibility, and cost. Ten vehicles were built to this final design. Tests conducted on prototypes and tests by others on the ten Phase 4 vehicles indicate successful achievement of the RSV goals. The results of developmental testing during Phase 3 are summarized as well as information from tests so far completed in Phase 4. Specific significant results include demonstration of survival of RSV occupants: in head-on collisions with both cars traveling at 40 mph (80 mph relative car-to-car speed); when struck on the side at 40 mph; and when hit from the rear at 45 mph. In addition, 50th percentile dummy pedestrians exhibited reduced injury levels from primary impacts at speeds up to 25 mph. Handling and braking exceeded the design specifications. Fuel economy was shown to be in the range of the 1985 requirements and emissions were shown to meet the 1978 California standard. Design of the vehicle is consistent with mass production techniques. Also, materials used in fabrication were chosen to minimize energy content, rare mineral requirements, and facilitate recycling for reuse. The results of the RSV tests in the U.S. and abroad prove the practicability of the design and substantiate its applicability to current production vehicles.

STUDY OF METHODS FOR INCREASING SAFETY BELT USE. STUDY REPORT

The recommendations and suggestions are summarized of a special committee convened to assess methods that have been or could be used to induce people to wear safety belts. The study included a comprehensive review of earlier evaluations of programs designed to promote seat belt use, and of consultations with public agencies, industry, private-sector organizations, and individuals. The committee concluded that no single program is likely to prove effective. Six key strategies were developed for Federal action: incentives to the states to enact child- and youth-occupant protection laws; compulsory seat belt use by on-the-job Federal employees; more productive use of Federal financial assistance for safety belt programs; identification of and publicity about the economic cost of not wearing seat belts; Federal testing of on-the-job safety belt use programs for industry, with possible insurance rate benefits; and involvement of Federal health agencies in safety belt programs. Methods for influencing safety belt behavior were identified as prescription (laws, regulations, and judicial decisions), economic incentives (insurance), changes in perception (by schools, health care centers, and the media), and personal and community influences (e.g. health care professionals).

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT

The handling and braking performance requirements for passenger cars towing trailers are based on the results of over 2000 combination-vehicle tests with eight trailers and three rear wheel drive tow cars (in 95 different configurations), over 500 tests with three trailers and two front wheel drive tow cars (in 38 different configurations), plus the results of previous trailer towing research. The proposed standards include recommendations for straight line braking performance, trailer swing stability, tow car steady turn stability, and combined brake in turn stability and performance. For straight line braking, the recommended performance criterion is 0.4 g deceleration of the combination-vehicle. A tow car weight based on trailer brake capability requirement is specified to meet this deceleration requirement. For trailer swing stability the safety-related performance measure is damping ratio. A minimum damping ratio of 0.15 (or 3/4 cycles to one-half amplitude) has been recommended. Test procedures and analysis are presented which can be used to determine damping ratio for each trailer. In this case, a minimum hitch load criterion based on tow car weight is suggested to insure performance compliance. For tow car stability a tentative performance criterion of maintaining a positive tow car understeer gradient up to and including 0.3 g cornering has been recommended. This requirement sets a limit on the maximum allowable hitch load for a given tow car weight and is a function of the load leveling torque applied by a weight equalizing (Class 3) hitch. These latter two handling requirements have been integrated into a single hitch load versus tow car weight graph unique to each trailer. Use of this graph by a user or manufacturer will define the proper hitch load range for a given tow car size and/or help specify the minimum weight tow car for a given trailer. A list of user guidelines is provided.

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 2: TECHNICAL REPORT FOR PHASE 1--REAR WHEEL DRIVE TOW CARS. FINAL REPORT

Suitable handling and braking performance requirements for rear-wheel drive passenger cars towing trailers are identified. This includes straight line braking, trailer swing stability, tow car steady turn stability, and combined brake-in-turn stability. Over 2000 combination-vehicle tests with eight trailers and three tow cars (in over 250 different configurations), plus the results of previous trailer towing research were then used to validate and/or revise the criteria and procedures. For straight line braking performance a combination-vehicle deceleration criterion of 0.4 g is recommended. A tow car weight requirement based on trailer brake capability is specified to meet the deceleration requirement. For trailer swing stability, a minimum damping ratio of 0.15 (or 3/4 cycles to 1/2 amplitude) is recommended. Test procedures and analysis curves are presented which can be used to determine damping ratios for each trailer. In this case a minimum hitch load criterion based on tow car weight is suggested to insure performance compliance. For tow car stability a tentative performance criterion of maintaining a positive tow car understeer up to and including 0.3 g cornering is recommended. This requirement sets a limit on the maximum allowable hitch load for a given weight tow car, and is a function of load leveling torque applied by a weight distributing hitch. These latter two handling requirements have been integrated into a hitch load versus tow car weight graph unique to each trailer. Use of this graph by a user or manufacturer wil define the proper hitch load range for a given tow car size and/ or help specify the minimum weight tow car for a given trailer

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 3: APPENDICES FOR PHASE 1. FINAL REPORT

All relevant specifications, measured parameter values, and ve hicle equipment descriptions are provided for the three tov vehicles and eight trailers used in the initial test program. Th tow vehicles and trailer specifications include loading recom mendations in the U-Haul trailer; tandem axle roll steer effect and their effect on the tow car stability factor; and the design o a horse trailer tandem axle. The full-scale instrumentation, tes equipment and test procedures are described, and a run lo summary provided. Straight line brake equations and test dat are presented, as well as trailer damping ratio and tow ca stability factor data.

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 4: TECHNICAL REPORT FOR PHASE 2--FRONT WHEEL DRIVE TOW CARS. FINAL REPORT

The handling and braking performance requirements are veri fied for passenger cars towing trailers. This includes straigh line braking, trailer swing stability, tow car steady turn stability and combined brake-in-turn stability. Over 500 combination vehicle tests with three trailers and two front wheel drive tov cars (in 34 different configurations), plus the results of previou trailer towing research, have been integrated into proposed per formance criteria, and a compliance format based on tow ca and trailer characteristics. For straight line braking perform ance, a combination-vehicle (CV) deceleration criteria of 0.4g i recommended. A tow car weight requirement based on traile brake capability is specified to meet this deceleration require ment. For unbraked trailers the tow car gross weight ratin should never be less than 1.5 times the trailer weight. For traile swing stability, a minimum damping ratio of 0.15 (or 3/4 cycle to 1/2 amplitude) is recommended. Test procedures and analysi curves are presented which can be used to determine dampin ratio for each trailer. In this case, a minimum hitch load crite rion based on tow car weight is suggested to insure performanc compliance. For tow car stability a tentative performance crite rion of maintaining a positive tow car understeer gradient up t and including 0.3g cornering is recommended. This requiremen sets a limit on the maximum allowable hitch load for a give weight tow car, and is a function of load leveling torque applied by a weight distributing hitch. The latter two handling requirements have been integrated into a hitch load versus tow car weight graph unique to each trailer. Use of this graph by a user or manufacturer will define the proper hitch load range for a given tow car size and/or help specify the minimum weight tow car for a given trailer.

ACCIDENT AVOIDANCE CAPABILITIES OF MOPEDS. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT

Moped response, performance, and accident avoidance capabilities are assessed. Moped design features are reviewed. Four instrumented vehicles were evaluated. Full scale tests included: steady turn, lane change, free control stability, roadway disturbance, open and closed loop braking, acceleration/top speed, and hill climb. Two wheeler test procedures and measures are presented, along with subjective evaluations. Sensitivity to operating variables are quantified. Potential safety-related handling problems were identified. A typical moped was modified for increased speed performance, and upgraded brake and tire components.

CONSUMER BEHAVIOR TOWARDS FUEL EFFICIENT VEHICLES. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT

An overview is provided of methodologies, results, and policy implications from an assessment of consumer behavior towards fuel-efficient vehicles designed to meet recently mandated Federal fuel economy standards. The study involves a comprehensive evaluation of existing nationwide survey data as well as the development of a major new econometric forecasting model of household vehicle type choice. The report includes both an assessment of consumers' current reported sentiments toward fuel-efficient vehicles and insights into expected future changes in household vehicle purchase behavior in response to changes in vehicle designs and prices, demographics, and the energy environment. Two forecasts of vehicle purchasing patterns through 1985 are developed based on an assumed schedule of vehicle design changes and alternative fuel price scenarios.

CONSUMER BEHAVIOR TOWARDS FUEL EFFICIENT VEHICLES. VOL. 2: CONSUMER SENTIMENTS TOWARDS FUEL EFFICIENT VEHICLES. FINAL REPORT

To meet the National Highway Traffic Safety Administration's (NHTSA) need to forecast consumer response to fuel-efficient motor vehicle designs, a statistical analysis was performed on a longitudinal series of Surveys of Consumer Sentiment, administered by the University of Michigan's Survey Research Center. A broad set of questions was examined concerning consumer attitudes towards energy policy in general and motor vehicle-related conservation efforts in particular. The survey analysis indicated a widespread awareness of the need to consume less in response to dwindling fossil fuel supplies, but pointed to a far smaller number of households willing to reduce their private gasoline consumption voluntarily either through changes in vehicle holdings or vehicle utilization. This discrepancy between public responsibility and private action underscores the importance of NHTSA'S Corporate Average Fuel Economy (CAFE) program. In terms of consumer reactions to vehicle design changes under the Title V mandate, the prevailing sentiment was that more fuel efficient vehicles could and would be introduced by domestic manufacturers. A significant majority of consumers favored sacrificing vehicle performance (i.e., engine size/power) rather than vehicle size as a means of meeting CAFE standards. The proportion of respondents favoring a downsized version of present models declines from 51% for full-size autos to only 17% for compacts. This has ominous implications for consumer acceptance of successively downsized automobiles. The survey results indicated that recent sales gains of light duty trucks are largely attributable to relatively young, well-educated white and blue-collar workers who used trucks as a substitute for auto transportation.

CUES
VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS
HS-805 051

CURRICULUM
EARLYRIDER EDUCATIONAL CURRICULUM. THE HEALTH PROFESSIONAL'S ROLE IS PROTECTING THE CHILD PASSENGER
HS-805 060

CUSHION
CRASH TEST PERFORMANCE OF A GUARDRAIL MEDIAN BARRIER AND TEMPORARY CONSTRUCTION-ZONE CRASH CUSHION (ABRIDGMENT)
HS-026 751

CYCLE
EVALUATION OF LUBRICANTS FOR JAPANESE SMALL AIR-COOLED TWO-CYCLE ENGINES
HS-026 720

FUTURE TWO-CYCLE ENGINE OIL DEVELOPMENT--A NEW CHALLENGE
HS-026 722

PERFORMANCE TEST METHODS FOR TWO-STROKE CYCLE ENGINE LUBRICANTS INCLUDING LEAN FUEL-OIL RATIO CONDITIONS
HS-026 721

CYCLIST
CYCLIST BEHAVIOR AT SIGNALIZED INTERSECTIONS
HS-026 734

DAYTIME
EVALUATION OF DAYTIME HIGH-VISIBILITY AIDS FOR MOTORCYCLISTS
HS-026 691

DEATH
DEATH AND INJURY ROAD ACCIDENTS IN NORTHERN IRELAND 1978
HS-026 680

DEFECT
SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 1. FINAL REPORT
HS-805 178

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 2. FINAL REPORT
HS-805 179

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 3. FINAL REPORT
HS-805 180

SYSTEMS FEASIBILITY STUDY: STATES' ASSISTANCE IN DEFECT RECALL CAMPAIGNS. VOL. 4. FINAL REPORT
HS-805 181

DELINEATION

EVALUATION OF DELINEATION SYSTEMS FOR THE NEW JERSEY BARRIER
HS-026 685

DEMONSTRATION

COMPARISON OF ORGANIZATIONAL AND OPERATIONAL ASPECTS OF FOUR VANPOOL DEMONSTRATION PROJECTS. FINAL REPORT
HS-026 683

DEPARTMENT

EVALUATION OF PROGRAMS IN THE DEPARTMENT OF TRANSPORTATION--AN ASSESSMENT. REPORT TO THE CONGRESS OF THE UNITED STATES BY THE COMPTROLLER GENERAL
HS-026 702

DEPRIVATION

EEG [ELECTROENCEPHALOGRAM] ALPHA CORRELATES OF ALCOHOL CONSUMPTION IN SMOKERS AND NONSMOKERS. EFFECTS OF SMOKING AND SMOKING DEPRIVATION
HS-026 678

DESCRIBE

MATHEMATICAL MODELS THAT DESCRIBE LATERAL DISPLACEMENT PHENOMENA (ABRIDGMENT)
HS-026 701

DESCRIBING

A COMPARISON BETWEEN FOUR COMPUTING MODELS OF DIFFERENT COMPLEXITY DESCRIBING THE STEERING BEHAVIOUR OF TWO-AXLED AUTOMOBILES
HS-026 633

DESIGN

ACCIDENTS INVOLVING HEAVY GOODS VEHICLES [COMMERCIAL TRUCKS] IN GREAT BRITAIN: FREQUENCIES AND DESIGN ASPECTS
HS-026 595

CALSPAN CHRYSLER RESEARCH SAFETY VEHICLE PHASE 3 FINAL DESIGN REPORT. VOL. 2: APPENDICES
HS-805 302

DESIGN AND DEVELOPMENT OF A SINGLE RAIL SHIFT OVERDRIVE (SROD) MANUAL TRANSMISSION
HS-026 662

EMISSION FACILITY DESIGN CRITERIA
HS-026 723

HIGHWAY DESIGN CONSISTENCY AND SYSTEMATIC DESIGN RELATED TO HIGHWAY SAFETY
HS-026 699

HUMAN FACTORS REQUIREMENTS FOR REAL-TIME MOTORIST INFORMATION DISPLAYS. VOL. 1, DESIGN GUIDE. FINAL REPORT
HS-026 582

NATIONAL ACCIDENT SAMPLING SYSTEM. SAMPLE DESIGN, PHASES 2 AND 3. EXECUTIVE SUMMARY. FINAL REPORT
HS-805 273

NATIONAL ACCIDENT SAMPLING SYSTEM. SAMPLE DESIGN, PHASES 2 AND 3. VOL 1: FINAL TECHNICAL REPORT
HS-805 274

DESIGNERS

ANTHROPOMETRIC SOURCE BOOK. VOL. 1: ANTHROPOMETRY FOR DESIGNERS
HS-026 741

DETECTION

EVALUATION OF THE HALO EFFECT IN SPEED DETECTION AND ENFORCEMENT (ABRIDGEMENT)
HS-026 672

VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS
HS-805 051

DETECTOR

THE DEVELOPMENT OF A MICROWAVE RADIOMETER FOR USE AS A HIGHWAY ICE DETECTOR. FINAL REPORT
HS-026 718

DEVELOPING

AUTOMOBILES AND CITIES: STRATEGIES FOR DEVELOPING COUNTRIES
HS-026 711

DEVICE

DEVELOPMENT OF A TEST METHODOLOGY FOR EVALUATING CRASH COMPATIBILITY AND AGGRESSIVENESS. TEST REPORT 2, 1975 FORD TORINO-TO-NHTSA TEST DEVICE. FINAL REPORT
HS-805 169

DEVELOPMENT OF A TEST METHODOLOGY FOR EVALUATING CRASH COMPATIBILITY AND AGGRESSIVENESS. TEST REPORT 3, 1975 VOLVO 244DL-TO-NHTSA TEST DEVICE. FINAL REPORT
HS-805 170

DEVICES

PERFORMANCE OF HIGHWAY SAFETY DEVICES
HS-026 746

TRAFFIC CONTROL DEVICES, VISIBILITY, AND GEOMETRICS
HS-026 684

DEW

PERFORMANCE OF SIGNS UNDER DEW AND FROST CONDITIONS (ABRIDGMENT)
HS-026 689

DIABETIC

DIABETIC FIGHTS FOR RIGHT TO GET A CLASS A LICENSE
HS-026 587

DIESEL

COMPARISON OF FUEL ECONOMY AND EMISSIONS FOR DIESEL AND GASOLINE POWERED TAXICABS. FINAL REPORT
HS-026 679

DIESEL ENGINE WEAR WITH SPIN-ON BY-PASS LUBE OIL FILTERS
HS-026 772

RESPONSE OF DIESEL COMBUSTION SYSTEMS TO INCREASE OF FUEL INJECTION RATE
HS-026 656

THERMODYNAMIC EFFICIENCY EVALUATION OF AN INDIRECT INJECTION DIESEL ENGINE
HS-026 658

TURBULENT AIR FLOW IN THE COMBUSTION BOWL OF A D. I. [DIRECT INJECTION] DIESEL ENGINE AND ITS EFFECT ON ENGINE PERFORMANCE
HS-026 659

TWO WAYS TO BOOST A LIGHT DUTY DIESEL
HS-026 657

DIGEST

TRAFFIC SAFETY '78. A DIGEST OF ACTIVITIES OF THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION
HS-805 100

DIMENSIONAL

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL CRASH VICTIM SIMULATION TUTORIAL SYSTEM: SELF-STUDY GUIDE. FINAL REPORT
HS-026 677

DIRECT

TURBULENT AIR FLOW IN THE COMBUSTION BOWL OF A D. I. [DIRECT INJECTION] DIESEL ENGINE AND ITS EFFECT ON ENGINE PERFORMANCE
HS-026 659

DIRECTIONAL

ON THE DIRECTIONAL REPSONSE CHARACTERISTICS OF HEAVY VEHICLES
HS-026 641

DISABLED

TREATMENTS OF OVERPASSES AND UNDERCROSSINGS FOR THE DISABLED: EARLY REPORT ON THE STATE OF THE ART (ABRIDGMENT)
HS-026 731

DISKS

TEMPERATURE CALCULATION AND PRACTICAL APPLICATION OF BRAKE DISKS (TEMPERATURBERECHNUNGEN VON BREMSSCHEIBEN UND IHRE PRAKTISCHE ANWENDUNG)
HS-026 767

DISPLACEMENT

MATHEMATICAL MODELS THAT DESCRIBE LATERAL DISPLACEMENT PHENOMENA (ABRIDGMENT)
HS-026 701

DISPLAYS

HUMAN FACTORS REQUIREMENTS FOR REAL-TIME MOTORIST INFORMATION DISPLAYS. VOL. 1, DESIGN GUIDE. FINAL REPORT
HS-026 582

DISPOSAL

IDENTIFICATION OF APPROACHES FOR THE CONTROL OF HEALTH, ENVIRONMENTAL, AND SAFETY HAZARDS ASSOCIATED WITH AIR BAG USE AND DISPOSAL. FINAL REPORT
HS-805 184

DISTRICT

TRAFFIC ANALYSIS ANNUAL REPORT, CALENDAR YEAR 1978 [DISTRICT OF COLUMBIA]
HS-026 569

DIVERSION

REAL-TIME DIVERSION OF FREEWAY TRAFFIC DURING MAINTENANCE OPERATIONS (ABRIDGMENT)
HS-026 728

DIY

SICK ENGINE? DON'T BE AFRAID OF A DIY [DO-IT-YOURSELF] VALVE JOB
HS-026 572

DOMAINS

AUTOMOBILE STABILITY; A STUDY OF THE DOMAINS OF ATTRACTION
HS-026 648

DOUBLE

COMPARISON OF CALIFORNIA ACCIDENT RATES FOR SINGLE AND DOUBLE TRACTOR-TRAILER COMBINATION TRUCKS. FINAL REPORT
HS-026 737

DRINKING

EVALUATION OF ALCOHOLISM TREATMENT PROGRAMS FOR DRINKING DRIVERS
HS-026 669

DRIVE

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 2: TECHNICAL REPORT FOR PHASE 1--REAR WHEEL DRIVE TOW CARS. FINAL REPORT
HS-805 327

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 4: TECHNICAL REPORT FOR PHASE 2--FRONT WHEEL DRIVE TOW CARS. FINAL REPORT
HS-805 329

EVALUATION OF THE FLYWHEEL DRIVE CONCEPT FOR PASSENGER VEHICLES
HS-026 664

DRIVER

DRIVER BEHAVIOR EFFECTS ON FUEL CONSUMPTION IN URBAN DRIVING
HS-026 713

DRIVER EDUCATION AND THE LICENSING OF 16 AND 17 YEAR OLDS
HS-026 760

DRIVER-VEHICLE INTERACTION WITH RESPECT TO STEERING CONTROLLABILITY
HS-026 650

PHYSICIAN REPORTING OF THE IMPAIRED DRIVER
HS-026 781

REANALYSIS OF CALIFORNIA DRIVER-VISION DATA: GENERAL FINDINGS (ABRIDGMENT)
HS-026 694

THE INFLUENCE OF VEHICLE CONTROL DYNAMICS ON DRIVER-VEHICLE PERFORMANCE
HS-026 651

DRIVERS

ACCIDENTS INVOLVING HANDICAPPED DRIVERS
HS-026 777

EVALUATION OF ALCOHOLISM TREATMENT PROGRAMS FOR DRINKING DRIVERS
HS-026 669

DRIVING

ADMINISTRATIVE ADJUDICATION OF DRIVING-WHILE-INTOXICATED OFFENSES
HS-026 671

DRIVER BEHAVIOR EFFECTS ON FUEL CONSUMPTION IN URBAN DRIVING
HS-026 713

DRUNKEN DRIVING IN FINLAND. LATE-NIGHT, WEEKEND INCIDENCE IN FIVE COMMUNITIES IN 1978
HS-026 778

HONEYWELL SAVES GAS WITH FEATHERFOOT. DRIVING EFFICIENCY AWARENESS PROGRAM
HS-026 573

THEORETICAL INVESTIGATION ON NON-STEADY-STATE DRIVING CONDITIONS OF A MOTOR VEHICLE
HS-026 635

VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS
HS-805 051

DRUNKEN

DRUNKEN DRIVING IN FINLAND. LATE-NIGHT, WEEKEND INCIDENCE IN FIVE COMMUNITIES IN 1978
HS-026 778

DUAL

DUAL PHASE STEEL PRODUCTION BUMPERS
HS-026 719

DUTY

TWO WAYS TO BOOST A LIGHT DUTY DIESEL
HS-026 657

DYNAMIC

DYNAMIC RESPONSE OF TRACTOR-SEMITRAILER VEHICLE TO RANDOM INPUT
HS-026 646

DYNAMIC TESTING OF MALLEABLE ALUMINUM TRANSFORMER BASES FOR HIGHWAY LUMINAIRES
HS-026 754

DYNAMICAL

DYNAMICAL ANALYSIS OF SUSPENSION SYSTEMS
HS-026 632

DYNAMICAL ASPECTS OF PASSENGER CARRYING VEHICLES USING CONTROLLED D.C. ELECTROMAGNETS
HS-026 653

THE BEHAVIOUR OF TRACTIVE UNITS AT SKIDDING WITH DIFFERENT KINDS OF PROPULSION AS A DYNAMICAL AND A STATISTICAL PROBLEM
HS-026 655

DYNAMICS

A GENERAL PURPOSE PROGRAM FOR THE SIMULATION OF VEHICLE-GUIDEWAY INTERACTION DYNAMICS
HS-026 637

PITCHING AND BOUNCING DYNAMICS EXCITED DURING ANTILOCK BRAKING OF A HEAVY TRUCK
HS-026 643

THE DYNAMICS OF VEHICLES ON ROADS AND ON TRACKS. PROCEEDINGS OF 5TH VSD [VEHICLE SYSTEM DYNAMICS]- 2ND IUTAM [INTERNATIONAL UNION OF THEORETICAL AND APPLIED MECHANICS] SYMPOSIUM HELD AT THE TECHNICAL UNIVERSITY VIENNA, AUSTRIA, SPETEMBER 19-23, 1977
HS-026 629

THE INFLUENCE OF VEHICLE CONTROL DYNAMICS ON DRIVER-VEHICLE PERFORMANCE
HS-026 651

EARLY

TREATMENTS OF OVERPASSES AND UNDERCROSSINGS FOR THE DISABLED: EARLY REPORT ON THE STATE OF THE ART (ABRIDGMENT)
HS-026 731

EARLYRIDER

EARLYRIDER EDUCATIONAL CURRICULUM. THE HEALTH PROFESSIONAL'S ROLE IS PROTECTING THE CHILD PASSENGER
HS-805 060

EARLYRIDER FACT BOOK [CHILD RESTRAINTS]
HS-805 057

EARLYRIDER LOAN A SEAT. HOW TO ESTABLISH AND OPERATE AN INFANT AND CHILD RESTRAINT LOAN PROGRAM
HS-805 056

EARLYRIDER PUBLICITY HANDBOOK [CHILD RESTRAINTS]
HS-805 059

THE EARLYRIDER SHOPPING GUIDE TO INFANT/CHILD AUTOMOBILE RESTRAINTS
HS-805 176

ECONOMIC

ECONOMIC ANALYSIS OF ALCOHOL SAFETY COUNTERMEASURES
HS-026 670

ENVIRONMENTAL IMPLICATIONS OF OPTIONS IN URBAN MOBILITY: OBSERVATIONS OF THE ENVIRONMENT COMMITTEE OF OECD [ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT]
HS-026 707

ECONOMY

AMBIENT TEMPERATURE, FUEL ECONOMY, EMISSIONS, AND TRIP LENGTH. FINAL REPORT
HS-803 668

COMPARISON OF FUEL ECONOMY AND EMISSIONS FOR DIESEL AND GASOLINE POWERED TAXICABS. FINAL REPORT
HS-026 679

MORE MILES FROM A BARREL OF CRUDE: A FRESH WAY OF LOOKING AT AUTOMOBILE FUEL ECONOMY SPURS BACK-TO-BASICS COMBUSTION RESEARCH
HS-026 764

POWERTRAIN MATCHING FOR BETTER FUEL ECONOMY
HS-026 660

EDUCATION

CALIFORNIA TRAFFIC SAFETY EDUCATION TASK FORCE REPORT
HS-026 739

DRIVER EDUCATION AND THE LICENSING OF 16 AND 17 YEAR OLDS
HS-026 760

MOTORCYCLE SAFETY EDUCATION AND LICENSING
HS-026 785

EDUCATIONAL

EARLYRIDER EDUCATIONAL CURRICULUM. THE HEALTH PROFESSIONAL'S ROLE IS PROTECTING THE CHILD PASSENGER
HS-805 060

EEG

EEG [ELECTROENCEPHALOGRAM] ALPHA CORRELATES OF ALCOHOL CONSUMPTION IN SMOKERS AND NONSMOKERS. EFFECTS OF SMOKING AND SMOKING DEPRIVATION
HS-026 678

EFFECTIVENESS

COST-EFFECTIVENESS MODEL FOR GUARDRAIL SELECTION (ABRIDGEMENT)
HS-026 747

EFFICIENCIES

AN EMISSION TEST FACILITY FOR MEASURING CATALYTIC CONVERTER EFFICIENCIES
HS-026 768

EFFICIENCY

HONEYWELL SAVES GAS WITH FEATHERFOOT. DRIVING EFFICIENCY AWARENESS PROGRAM
HS-026 573

THERMODYNAMIC EFFICIENCY EVALUATION OF AN INDIRECT INJECTION DIESEL ENGINE
HS-026 658

EFFICIENT

CONSUMER BEHAVIOR TOWARDS FUEL EFFICIENT VEHICLES. EXECUTIVE SUMMARY. FINAL REPORT
HS-804 775

CONSUMER BEHAVIOR TOWARDS FUEL EFFICIENT VEHICLES. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT
HS-805 339

CONSUMER BEHAVIOR TOWARDS FUEL EFFICIENT VEHICLES. VOL. 2: CONSUMER SENTIMENTS TOWARDS FUEL EFFICIENT VEHICLES. FINAL REPORT
HS-805 340

ELECTRA

BASELINE TESTS OF THE ELECTRA-VAN MULTIPURPOSE ELECTRIC VAN
HS-026 740

ELECTRIC

BASELINE TESTS OF THE ELECTRA-VAN MULTIPURPOSE ELECTRIC VAN
HS-026 740

ELECTRICAL

AMBULANCE ELECTRICAL SYSTEM STUDY. FINAL REPORT
HS-805 128

ELECTROENCEPHALOGRAM

EEG [ELECTROENCEPHALOGRAM] ALPHA CORRELATES OF ALCOHOL CONSUMPTION IN SMOKERS AND NONSMOKERS. EFFECTS OF SMOKING AND SMOKING DEPRIVATION
HS-026 678

ELECTROMAGNETS

DYNAMICAL ASPECTS OF PASSENGER CARRYING VEHICLES USING CONTROLLED D.C. ELECTROMAGNETS
HS-026 653

ELECTRONIC

PLANNING FOR AUTOMOTIVE ELECTRONIC INSTRUMENTATION
HS-026 665

EMERGENCY

INFORMATION TRANSFER CHARACTERISTICS OF MOVING LIGHT SIGNALS [ON EMERGENCY VEHICLES]
HS-026 715

EMISSION

AN EMISSION TEST FACILITY FOR MEASURING CATALYTIC CONVERTER EFFICIENCIES
HS-026 768

EMISSION FACILITY DESIGN CRITERIA
HS-026 723

EMISSIONS

AMBIENT TEMPERATURE, FUEL ECONOMY, EMISSIONS, AND TRIP LENGTH. FINAL REPORT
HS-803 668

COMPARISON OF FUEL ECONOMY AND EMISSIONS FOR DIESEL AND GASOLINE POWERED TAXICABS. FINAL REPORT
HS-026 679

ENERGY

ENERGY CONSERVATION POTENTIAL OF LAND-BASED RECREATIONAL MOTOR VEHICLES. FINAL REPORT
HS-805 205

EXPERIMENTAL EVALUATION OF A PORTABLE ENERGY-ABSORBING SYSTEM FOR HIGHWAY SERVICE VEHICLES (ABRIDGMENT)
HS-026 750

ENFORCEMENT

ENFORCEMENT OF THE NATIONAL MAXIMUM SPEED LIMIT. ENFORCEMENT PRACTICES AND PROCEDURES. FINAL TECHNICAL REPORT
HS-805 175

EVALUATION OF THE HALO EFFECT IN SPEED DETECTION AND ENFORCEMENT (ABRIDGEMENT)
HS-026 672

GUIDE TO HIGH SPEED PATROL CAR TIRES (LAW ENFORCEMENT EQUIPMENT TECHNOLOGY)
HS-026 681

ENGINE

COLD-AIR PERFORMANCE OF FREE POWER TURBINE DESIGNED FOR 112-KILOWATT AUTOMOTIVE GAS-TURBINE ENGINE. 2. EFFECTS OF VARIABLE STATOR-VANE-CHORD SETTING ANGLE ON TURBINE PERFORMANCE. FINAL REPORT
HS-026 704

COMPUTERIZED FACILITY FOR ENGINE DEVELOPMENT
HS-026 769

DIESEL ENGINE WEAR WITH SPIN-ON BY-PASS LUBE OIL FILTERS
HS-026 772

FUTURE TWO-CYCLE ENGINE OIL DEVELOPMENT–A NEW CHALLENGE

HS-026 681

GUIDE TO THE MOTOR INDUSTRY OF JAPAN 1979
HS-026 580

HUMAN FACTORS REQUIREMENTS FOR REAL-TIME MOTORIST INFORMATION DISPLAYS. VOL. 1, DESIGN GUIDE. FINAL REPORT
HS-026 582

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL CRASH VICTIM SIMULATION TUTORIAL SYSTEM: SELF-STUDY GUIDE. FINAL REPORT
HS-026 677

THE EARLYRIDER SHOPPING GUIDE TO INFANT/CHILD AUTOMOBILE RESTRAINTS
HS-805 176

TWO-WAY LEFT-TURN LANES: STATE-OF-THE-ART OVERVIEW AND IMPLEMENTATION GUIDE
HS-026 697

GUIDEWAY

A GENERAL PURPOSE PROGRAM FOR THE SIMULATION OF VEHICLE-GUIDEWAY INTERACTION DYNAMICS
HS-026 637

PERFORMANCE OF STEERING CONTROLLERS FOR AUTOMATED GUIDEWAY TRANSIT VEHICLES
HS-026 638

HALO

EVALUATION OF THE HALO EFFECT IN SPEED DETECTION AND ENFORCEMENT (ABRIDGEMENT)
HS-026 672

HANDBOOK

ANTHROPOMETRIC SOURCE BOOK. VOL. 2: A HANDBOOK OF ANTHROPOMETRIC DATA
HS-026 742

EARLYRIDER PUBLICITY HANDBOOK [CHILD RESTRAINTS]
HS-805 059

HANDICAPPED

ACCIDENTS INVOLVING HANDICAPPED DRIVERS
HS-026 777

HANDLING

COMPUTING AND MEASUREMENTS OF THE HANDLING QUALITITES OF THE BELTED TYRE [TIRE]
HS-026 636

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT
HS-805 326

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 2: TECHNICAL REPORT FOR PHASE 1--REAR WHEEL DRIVE TOW CARS. FINAL REPORT
HS-805 327

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 3: APPENDICES FOR PHASE 1. FINAL REPORT
HS-805 328

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 4: TECHNICAL REPORT FOR PHASE 2--FRONT WHEEL DRIVE TOW CARS. FINAL REPORT
HS-805 329

HAVOC

IT'S TIME TO "CRY HAVOC"
HS-026 780

HAZARD

ROADSIDE HAZARD MODEL (ABRIDGMENT)
HS-026 695

HAZARDS

IDENTIFICATION OF APPROACHES FOR THE CONTROL OF HEALTH, ENVIRONMENTAL, AND SAFETY HAZARDS ASSOCIATED WITH AIR BAG USE AND DISPOSAL. FINAL REPORT
HS-805 184

STUDIES OF ROADSIDE HAZARDS FOR PROJECTING FATAL CRASH SITES
HS-026 668

HEALTH

ALCOHOL AVAILABILITY, CONSUMPTION AND THE INCIDENCE OF ALCOHOL-RELATED SOCIAL AND HEALTH PROBLEMS IN MICHIGAN. FINAL REPORT
HS-026 783

ALCOHOL AVAILABILITY, CONSUMPTION AND THE INCIDENCE OF ALCOHOL-RELATED SOCIAL AND HEALTH PROBLEMS IN MICHIGAN. EXECUTIVE SUMMARY. FINAL REPORT
HS-026 784

EARLYRIDER EDUCATIONAL CURRICULUM. THE HEALTH PROFESSIONAL'S ROLE IS PROTECTING THE CHILD PASSENGER
HS-805 060

IDENTIFICATION OF APPROACHES FOR THE CONTROL OF HEALTH, ENVIRONMENTAL, AND SAFETY HAZARDS ASSOCIATED WITH AIR BAG USE AND DISPOSAL. FINAL REPORT
HS-805 184

HEARING

AUTOMOTIVE DEVELOPMENT. HEARING ON GOVERNMENT/INDUSTRY ROLES IN FUTURE AUTOMOTIVE DEVELOPMENT, MARCH 23, 1979
HS-026 586

HEAVY

ACCIDENTS INVOLVING HEAVY GOODS VEHICLES [COMMERCIAL TRUCKS] IN GREAT BRITAIN: FREQUENCIES AND DESIGN ASPECTS
HS-026 595

IMPROVING ANTI-ROLL PROPERTIES OF SEMITRAILERS, ROAD TRACTORS, AND HEAVY TRUCKS
HS-026 675

ON THE DIRECTIONAL REPSONSE CHARACTERISTICS OF HEAVY VEHICLES
HS-026 641

PITCHING AND BOUNCING DYNAMICS EXCITED DURING ANTILOCK BRAKING OF A HEAVY TRUCK
HS-026 643

PREDICTION OF THE FUEL CONSUMPTION OF HEAVY GOODS VEHICLES BY COMPUTER SIMULATION
HS-026 592

HEIGHT

A THEORETICAL MODEL TO ESTIMATE SOME ERGONOMIC PARAMETERS FROM AGE, HEIGHT AND WEIGHT
HS-026 590

HELD

THE DYNAMICS OF VEHICLES ON ROADS AND ON TRACKS. PROCEEDINGS OF 5TH VSD [VEHICLE SYSTEM DYNAMICS]- 2ND IUTAM [INTERNATIONAL UNION OF THEORETICAL AND APPLIED MECHANICS] SYMPOSIUM HELD AT THE TECHNICAL UNIVERSITY VIENNA, AUSTRIA, SPETEMBER 19-23, 1977
HS-026 629

HELMET

A REPORT TO THE CONGRESS ON THE EFFECT OF MOTORCYCLE HELMET USE LAW REPEAL--A CASE FOR HELMET USE
HS-805 312

HIGHWAY

ADVANCE ROAD SIGN MESSAGES FOR HIGHWAY ADVISORY RADIO SYSTEMS (ABRIDGMENT)
HS-026 726

DYNAMIC TESTING OF MALLEABLE ALUMINUM TRANSFORMER BASES FOR HIGHWAY LUMINAIRES
HS-026 754

EXPERIMENTAL EVALUATION OF A PORTABLE ENERGY-ABSORBING SYSTEM FOR HIGHWAY SERVICE VEHICLES (ABRIDGMENT)
HS-026 750

HIGHWAY DESIGN CONSISTENCY AND SYSTEMATIC DESIGN RELATED TO HIGHWAY SAFETY
HS-026 699

IMPACT OF HIGHWAY METRICATION ON TRAFFIC ACCIDENTS AND LONG-TERM TRENDS IN VEHICLE SPEEDS FOR ROADS WITH RESULTANT INCREASED SPEED LIMITS
HS-026 717

PERFORMANCE OF HIGHWAY SAFETY DEVICES
HS-026 746

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, JANUARY 1, 1979 TO DECEMBER 31, 1979
HS-805 265

THE DEVELOPMENT OF A MICROWAVE RADIOMETER FOR USE AS A HIGHWAY ICE DETECTOR. FINAL REPORT
HS-026 718

TRAFFIC SAFETY '78. A DIGEST OF ACTIVITIES OF THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION
HS-805 100

1978 ACCIDENT DATA. TRAFFIC VOLUMES AND MILEAGE ON THE STATE HIGHWAY SYSTEM BY ROUTE, COUNTY AND MUNICIPALITY [NEW JERSEY]
HS-026 667

HIGHWAYS

ANALYSIS OF THE RELATION OF ACCIDENTS AND THE 88-KM/H (55-MPH) SPEED LIMIT ON ARIZONA HIGHWAYS (ABRIDGMENT)
HS-026 673

NORTH CAROLINA'S BICYCLING HIGHWAYS
HS-026 736

SELECTION OF MEDIAN TREATMENTS FOR EXISTING ARTERIAL HIGHWAYS
HS-026 698

HISTORIES

THE EARLYRIDER SHOPPING GUIDE TO INFANT/CHILD AUTOMOBILE RESTRAINTS
HS-805 176

INFORMATION

HUMAN FACTORS REQUIREMENTS FOR REAL-TIME MOTORIST INFORMATION DISPLAYS. VOL. 1, DESIGN GUIDE. FINAL REPORT
HS-026 582

INFORMATION TRANSFER CHARACTERISTICS OF MOVING LIGHT SIGNALS [ON EMERGENCY VEHICLES]
HS-026 715

ROAD USER INFORMATION NEEDS, PEDESTRIAN MOVEMENT, AND BICYCLE TRAVEL PATTERNS
HS-026 724

INJECTION

RESPONSE OF DIESEL COMBUSTION SYSTEMS TO INCREASE OF FUEL INJECTION RATE
HS-026 656

THERMODYNAMIC EFFICIENCY EVALUATION OF AN INDIRECT INJECTION DIESEL ENGINE
HS-026 658

TURBULENT AIR FLOW IN THE COMBUSTION BOWL OF A D. I. [DIRECT INJECTION] DIESEL ENGINE AND ITS EFFECT ON ENGINE PERFORMANCE
HS-026 659

INJURY

DEATH AND INJURY ROAD ACCIDENTS IN NORTHERN IRELAND 1978
HS-026 680

INJURY CODING MANUAL 1980. FINAL REPORT
HS-805 298

INNOVATIONS

URBAN PUBLIC TRANSPORT: SERVICE INNOVATIONS IN OPERATIONS, PLANNING AND TECHNOLOGY
HS-026 708

INPUT

DYNAMIC RESPONSE OF TRACTOR-SEMITRAILER VEHICLE TO RANDOM INPUT
HS-026 646

INSPECTION

COMPARISON OF PRE AND POST ROAD TEST ULTRASONIC INSPECTION RESULTS ON 134 PASSENGER TIRES. FINAL REPORT
HS-805 029

CORRELATION BETWEEN ULTRASONIC NONDESTRUCTIVE INSPECTION AND WHEEL TEST OF 34 RETREADED TIRES. FINAL REPORT
HS-805 030

DETERMINATION OF TIRE QUALITY FROM NONDESTRUCTIVE INSPECTION. FINAL REPORT
HS-804 828

INSTRUMENTATION

PLANNING FOR AUTOMOTIVE ELECTRONIC INSTRUMENTATION
HS-026 665

WEIGH-IN-MOTION INSTRUMENTATION [TRUCK WEIGHT]. FINAL REPORT
HS-026 682

INTENSITY

RELATION BETWEEN SIGN LUMINANCE AND SPECIFIC INTENSITY OF REFLECTIVE MATERIALS
HS-026 690

INTERACTION

A GENERAL PURPOSE PROGRAM FOR THE SIMULATION OF VEHICLE-GUIDEWAY INTERACTION DYNAMICS
HS-026 637

DRIVER-VEHICLE INTERACTION WITH RESPECT TO STEERING CONTROLLABILITY
HS-026 650

INTERIM

MULTILEVEL STUDY OF ACCIDENT CAUSATION AND AVOIDANCE: PHASE 1A PLANNING REPORT. INTERIM REPORT
HS-805 177

VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS
HS-805 051

INTERNATIONAL

THE AUTOMOBILE AND THE ENVIRONMENT: AN INTERNATIONAL PERSPECTIVE
HS-026 706

THE DYNAMICS OF VEHICLES ON ROADS AND ON TRACKS. PROCEEDINGS OF 5TH VSD [VEHICLE SYSTEM DYNAMICS]- 2ND IUTAM [INTERNATIONAL UNION OF THEORETICAL AND APPLIED MECHANICS] SYMPOSIUM HELD AT THE TECHNICAL UNIVERSITY VIENNA, AUSTRIA, SPETEMBER 19-23, 1977
HS-026 629

INTERSECTIONS

COMPREHENSIVE EVALUATION OF NONSIGNALIZED CONTROL AT LOW-VOLUME INTERSECTIONS (ABRIDGMENT)
HS-026 687

CYCLIST BEHAVIOR AT SIGNALIZED INTERSECTIONS
HS-026 734

SIGNALIZATION OF HIGH-SPEED, ISOLATED INTERSECTIONS
HS-026 692

INTOXICATED

ADMINISTRATIVE ADJUDICATION OF DRIVING-WHILE-INTOXICATED OFFENSES
HS-026 671

VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS
HS-805 051

INVENTORY

COMPUTERIZED INVENTORY AND PRIORITY ANALYSIS FOR ROADSIDE OBSTACLES (ABRIDGMENT)
HS-026 748

INVESTIGATION

COLLISION AVOIDANCE RADAR BRAKING SYSTEMS INVESTIGATION--PHASE 3 STUDY. FINAL TECHNICAL REPORT
HS-805 049

RELATION BETWEEN ROADSIDE SIGNS AND TRAFFIC ACCIDENTS: FIELD INVESTIGATION
HS-026 725

THEORETICAL INVESTIGATION ON NON-STEADY-STATE DRIVING CONDITIONS OF A MOTOR VEHICLE
HS-026 635

IRELAND

A MODEL OF THE SEMI-TRAILER VEHICLE INCLUDING ROLL MODES
HS-026 642

COMPARISON OF CALIFORNIA ACCIDENT RATES FOR SINGLE AND DOUBLE TRACTOR-TRAILER COMBINATION TRUCKS. FINAL REPORT
HS-026 737

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT
HS-805 326

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 2: TECHNICAL REPORT FOR PHASE 1--REAR WHEEL DRIVE TOW CARS. FINAL REPORT
HS-805 327

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 3: APPENDICES FOR PHASE 1. FINAL REPORT
HS-805 328

DEVELOPMENT OF CAR/TRAILER HANDLING AND BRAKING STANDARDS. VOL. 4: TECHNICAL REPORT FOR PHASE 2--FRONT WHEEL DRIVE TOW CARS. FINAL REPORT
HS-805 329

THE STEADY-STATE-BEHAVIOUR OF A TRUCK-TRAILER-SYSTEM CARRYING RIGID OR LIQUID LOAD
HS-026 647

TRANSFER

INFORMATION TRANSFER CHARACTERISTICS OF MOVING LIGHT SIGNALS [ON EMERGENCY VEHICLES]
HS-026 715

TRANSFORMER

DYNAMIC TESTING OF MALLEABLE ALUMINUM TRANSFORMER BASES FOR HIGHWAY LUMINAIRES
HS-026 754

TRANSIENT

THE INFLUENCE OF THE STRUCTURE OF AUTOMOBILE MODELS AND TYRE [TIRE] CHARACTERISTICS ON THE THEORETICAL RESULTS OF STEADY-STATE AND TRANSIENT VEHICLE PERFORMANCE
HS-026 631

TRANSIENT CONTROL RESPONSE OF AUTOMOBILES
HS-026 634

TRANSIT

PERFORMANCE OF STEERING CONTROLLERS FOR AUTOMATED GUIDEWAY TRANSIT VEHICLES
HS-026 638

TRANSMISSION

DESIGN AND DEVELOPMENT OF A SINGLE RAIL SHIFT OVERDRIVE (SROD) MANUAL TRANSMISSION
HS-026 662

TRANSPORT

ACCESSIBILITY MEASURES USED TO APPRAISE TRANSPORT SYSTEM PERFORMANCE
HS-026 577

SURFACE TRANSPORT REGULATION AND RAILROAD PLANNING
HS-026 765

URBAN PUBLIC TRANSPORT: SERVICE INNOVATIONS IN OPERATIONS, PLANNING AND TECHNOLOGY
HS-026 708

TRANSPORTATION

CONSOLIDATED TRANSPORTATION PROGRAM (1978-1982), MARYLAND
HS-026 703

EVALUATION OF PROGRAMS IN THE DEPARTMENT OF TRANSPORTATION--AN ASSESSMENT. REPORT TO THE CONGRESS OF THE UNITED STATES BY THE COMPTROLLER GENERAL
HS-026 702

RELATION BETWEEN LIGHTING PARAMETERS AND TRANSPORTATION PERFORMANCE
HS-026 693

TRANSPORTATION AND THE FUTURE
HS-026 738

TRAVEL

CAR POOLING: TRAVEL TO WORK AT AN ISOLATED SITE
HS-026 594

ROAD USER INFORMATION NEEDS, PEDESTRIAN MOVEMENT, AND BICYCLE TRAVEL PATTERNS
HS-026 724

SOME CHARACTERISTICS OF BICYCLE TRAVEL AND ACCIDENTS IN TOWNS [IN ISRAEL]
HS-026 733

TREATMENT

EVALUATION OF ALCOHOLISM TREATMENT PROGRAMS FOR DRINKING DRIVERS
HS-026 669

TREATMENTS

SELECTION OF MEDIAN TREATMENTS FOR EXISTING ARTERIAL HIGHWAYS
HS-026 698

TREATMENTS OF OVERPASSES AND UNDERCROSSINGS FOR THE DISABLED: EARLY REPORT ON THE STATE OF THE ART (ABRIDGMENT)
HS-026 731

TRENDS

IMPACT OF HIGHWAY METRICATION ON TRAFFIC ACCIDENTS AND LONG-TERM TRENDS IN VEHICLE SPEEDS FOR ROADS WITH RESULTANT INCREASED SPEED LIMITS
HS-026 717

RECENT TRENDS IN VAN AND SMALL TRUCK SAFETY
HS-026 674

VEHICLE SIZE AND WEIGHT REGULATIONS, PERMIT OPERATION, AND FUTURE TRENDS
HS-026 766

TRIP

AMBIENT TEMPERATURE, FUEL ECONOMY, EMISSIONS, AND TRIP LENGTH. FINAL REPORT
HS-803 668

TRUCK

HOW TO BUY A BODY FOR A UTILITY TRUCK
HS-026 771

HOW TO BUY A TRUCK FRAME FOR A UTILITY VEHICLE
HS-026 770

PITCHING AND BOUNCING DYNAMICS EXCITED DURING ANTILOCK BRAKING OF A HEAVY TRUCK
HS-026 643

RECENT TRENDS IN VAN AND SMALL TRUCK SAFETY
HS-026 674

THE STEADY-STATE-BEHAVIOUR OF A TRUCK-TRAILER-SYSTEM CARRYING RIGID OR LIQUID LOAD
HS-026 647

TRUCK, BUS, AND MOTORCYCLE SAFETY STATUS METHODOLOGY. VOL. 1: TECHNICAL SUMMARY. FINAL REPORT
HS-805 192

TRUCK, BUS, AND MOTORCYCLE SAFETY STATUS METHODOLOGY. VOL. 2: TECHNICAL REPORT. FINAL REPORT
HS-805 193

WEIGH-IN-MOTION INSTRUMENTATION [TRUCK WEIGHT]. FINAL REPORT
HS-026 682

TRUCKS

ACCIDENTS INVOLVING HEAVY GOODS VEHICLES [COMMERCIAL TRUCKS] IN GREAT BRITAIN: FREQUENCIES AND DESIGN ASPECTS
HS-026 595

COMPARISON OF CALIFORNIA ACCIDENT RATES FOR SINGLE AND DOUBLE TRACTOR-TRAILER COMBINATION TRUCKS. FINAL REPORT
HS-026 737

IMPROVING ANTI-ROLL PROPERTIES OF SEMI-TRAILERS, ROAD TRACTORS, AND HEAVY TRUCKS
HS-026 675

STUDY OF THE EFFECTS OF APPLYING FEDERAL MOTOR VEHICLE SAFETY STANDARD 201 TO LIGHT TRUCKS AND VANS. FINAL REPORT
HS-805 162

STUDY OF THE EFFECTS OF APPLYING FEDERAL MOTOR VEHICLE SAFETY STANDARDS 203 AND 204 TO LIGHT TRUCKS AND VANS. FINAL REPORT
HS-805 163

TUNNELS

SPEED/FLOW RELATIONSHIPS IN ROAD TUNNELS
HS-026 591

TURBINE

COLD-AIR PERFORMANCE OF FREE POWER TURBINE DESIGNED FOR 112-KILOWATT AUTOMOTIVE GAS-TURBINE ENGINE. 2. EFFECTS OF VARIABLE STATOR-VANE-CHORD SETTING ANGLE ON TURBINE PERFORMANCE. FINAL REPORT
HS-026 704

TURBULENT

TURBULENT AIR FLOW IN THE COMBUSTION BOWL OF A D. I. [DIRECT INJECTION] DIESEL ENGINE AND ITS EFFECT ON ENGINE PERFORMANCE
HS-026 659

TURN

TWO-WAY LEFT-TURN LANES: STATE-OF-THE-ART OVERVIEW AND IMPLEMENTATION GUIDE
HS-026 697

TUTORIAL

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL CRASH VICTIM SIMULATION TUTORIAL SYSTEM: SELF-STUDY GUIDE. FINAL REPORT
HS-026 677

TYPE

FEASIBILITY OF A FOLLOWER TYPE TRAFFIC STRING CONTROL
HS-026 639

TYPES

PROPERTIES OF GUARDRAIL POSTS FOR VARIOUS SOIL TYPES
HS-026 752

TYRE

COMPUTING AND MEASUREMENTS OF THE HANDLING QUALITITES OF THE BELTED TYRE [TIRE]
HS-026 636

THE INFLUENCE OF THE STRUCTURE OF AUTOMOBILE MODELS AND TYRE [TIRE] CHARACTERISTICS ON THE THEORETICAL RESULTS OF STEADY-STATE AND TRANSIENT VEHICLE PERFORMANCE
HS-026 631

ULTRASONIC

COMPARISON OF PRE AND POST ROAD TEST ULTRASONIC INSPECTION RESULTS ON 134 PASSENGER TIRES. FINAL REPORT
HS-805 029

CORRELATION BETWEEN ULTRASONIC NONDESTRUCTIVE INSPECTION AND WHEEL TEST OF 34 RETREADED TIRES. FINAL REPORT
HS-805 030

UNDERCROSSINGS

TREATMENTS OF OVERPASSES AND UNDERCROSSINGS FOR THE DISABLED: EARLY REPORT ON THE STATE OF THE ART (ABRIDGMENT)
HS-026 731

UNION

THE DYNAMICS OF VEHICLES ON ROADS AND ON TRACKS. PROCEEDINGS OF 5TH VSD [VEHICLE SYSTEM DYNAMICS]- 2ND IUTAM [INTERNATIONAL UNION OF THEORETICAL AND APPLIED MECHANICS] SYMPOSIUM HELD AT THE TECHNICAL UNIVERSITY VIENNA, AUSTRIA, SPETEMBER 19-23, 1977
HS-026 629

Highway Safety Literature

U.S. Department of Transportation **National Highway Traffic Safety Administration**

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Sa
Administration (NHTSA). It is divided into the following sections: Abstract Citations, contai
bibliographical information and abstracts; and an Index to Abstracts, including a keyword-o
context (KWOC) list of words in the title, followed by the full title and HS number (our acces
number); an Author Index; a Corporate Author Index; a Contract Number Index; and a R
Number Index. In those months when information on contracts recently awarded is availab
section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Tech
Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the E
at the address below for inclusion in the collection and abstracting in this publication. Pl
indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for i
mation. Views expressed are those of the authors and not necessarily those of the Admini
tion. Reference to brand names, equipment, models or companies does not imply endorseme
NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Satety Literature** may be addressed to

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive
gineers, Dept. HSL, 400 C

listed in the individual citatio

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED B MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning t maximum amount of brake pedal force that automobile drive were able to sustain over a period of ten seconds. Subje were told to apply the brakes in the test car as they would i panic stop, and to exert as much force as possible on t pedal over the entire ten second test period. A total of 84 su jects were tested, including 42 males and 42 females. T results indicated that there is a wide distribution of valu which characterizes the pedal force that the subjects were a to generate. Male subjects produced generally higher forc than did females. Over half the women tested were unable exert more than 150 lbs. of force with either foot alone, b when both feet were applied to the pedal, force levels rose s nificantly.

NHTSA accession number	HS-018 924
Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflati pressure are deduced by assuming the bias tire as a composi structure of a bias-laminated, toroidal membrane shell a rigorously taking three displacement components into co sideration. The point collocation method is used to solve derived system of differential equations with variable coef cients. It is found that the lowest natural frequencies calc lated for two kinds of bias tire agree well with the correspon ing experimental results in a wide range of inflation pressur Results of the approximate analysis show that the influenc of the in-plane inertia forces on natural frequency may be co sidered small, but the influences of in-plane displacements a large, particularly on the natural frequency of the tire und low inflation pressure.

RIDE QUALITY RATINGS AS A FUNCTION OF SENSORY INPUT

An experiment was conducted to investigate the effects of extraneous or deprived sensory input on ratings of ride quality. Fifty-four subjects were driven over each of nine different 365-meter road sections in groups of three and were asked to rate each section on the basis of ride comfort. The independent variables were sensory mode, condition, and road surface roughness. Auditory and visual sensory modes were employed, with the order of sensory mode counterbalanced. Trial runs on the road were divided into three blocks of three consecutive trials: control condition; extraneous stimuli condition; and deprived sensory input condition. The road surface ranged in condition from smooth to rough. Results demonstrated that ride quality ratings under the deprived sensory input condition were more accurate than other experimental conditions. Smooth road surfaces were rated better and rough road surfaces were rated worse than the control. Ratings in the extraneous stimuli condition were less accurate than the control condition and ratings of ride quality were uniformly rougher than the control for all road surfaces. It is recommended that further study include the vehicle as an important experimental variable.

CONSIDERATIONS FOR REARVIEW MIRROR SYSTEMS FOR LARGE TRUCKS

Comments are presented relating to the Proposed Rulemaking in Docket No. 71-3a; Notice 4, which would amend Federal Motor Vehicle Safety Standard 111, Rearview Mirror Systems. Field of view, weather effects, alignment and adjustment, and convexity are addressed as they pertain to large trucks. An addendum to the original comments presents specific recommendations for modifications to the proposed rule. In terms of field of view, the rule should be revised to ensure that significant objects to the right of the truck cannot be hidden from view. This could be accomplished by defining an appropriate area or target object forward of the designated field YR which should be viewable by either direct or indirect means. Concerning alignment and adjustment, a provision similar to S5.3.1.6(b) needs to be developed for those trucks designed to meet S.5.3.2.1 through S.5.3.2.6. This would require that such vehicles also have an extended view of a designated target SR, or adjustment or locking features on right-hand mirrors. There seems no need to establish a maximum radius of curvature for convex mirrors (60 is mentioned in proposed rule). It is recommended that the proposed minimum radius of 20 in. for truck convex mirrors be reviewed to determine whether it might be increased to at least 30 in. The rule should contain provisions to ensure that ice or mist can be readily removed without the driver leaving his seat.

THE EVIDENTIAL VALUE OF AUTOMOBILE PAINT CHIPS

A survey of 200 random automobile paint chips with a standard forensic laboratory examination procedure (microscopic examination, solvent reactivity tests, instrumental analysis of organic constituents, and instrumental analysis of inorganic constituents) served to differentiate all samples. Specimen characteristics were tabulated throughout the examination to evaluate their frequency of occurrence in samples similar to those encountered in case work. Ninety-four percent of the samples were differentiated by microscopic examination and solvent reactivity tests. Of the remaining 6% that were undifferentiated, none of the paint chips had more than three layers. This observation leads to the conclusion that the probability of two paint chips originating from different sources is extremely remote when they have numerous layers (six or more) consistent in color, tint, type of finish, layer thickness, and reaction to acetone, sulfuric acid, and diphenylamine test solution. Ninety-seven percent of the samples were differentiated without the use of elemental analysis. For maximum differentiation capability, at least one instrumental analysis technique for organic components and one for elemental components should be incorporated into the analytical scheme when sample size permits. A review of the literature revealed the lack of frequency of occurrence studies for automobile paint evidence. Additional studies, similar to the present one, are being initiated to further assess the statistical value of this type of class evidence.

LIGHT AND HEAVY TRUCKS LOSE WEIGHT, GAIN PAYLOAD

The design developed by the Rockwell International Plastics Div. which allows the entire body of a pickup truck to be made of sheet molded compound fiberglass, thereby reducing the total weight by some 500 lb (227 kg), has not been enthusiastically adopted by engineers, partly because of the uncertainty of mileage standards for trucks in the 1982 and subsequent model years. The auto and truck makers are moving much more slowly in adding major plastic and aluminum parts because of the cost of these materials, and their need for extended equipment and facilities. Rockwell is now producing fiberglass hood-and-fender assemblies for Ford, Mack, International Harvester, and GMC Truck and Coach. These fiberglass components were adopted primarily because of corrosion resistance and lower initial tooling costs, with weight reduction a less important factor. Additional advantages include the ability to use six individual plastic pieces instead of 21 for a steel front end, a tilt feature for ease of maintenance, different styling lines, molding of storage boxes on the outside of the truck, and more frequent styling changes. A major obstacle to the construction of a large number of fiberglass pickups is the current lack of capacity (compression molding presses). Other Rockwell developments include several new or substantially modified components and systems recently introduced in its Truck Axle Div.: an SQHP tandem axle with aluminum carrier castings, a front axle in the 12,000 lb class with an aluminum beam, an FDS series of heavy-duty front driving axles, and an inter-axle differential locking system.

OPTIONAL SAFETY DEVICES: HOW STRICT THE LIABILITY?

The development of legal principles is examined in a narrow area of a manufacturer's legal responsibility under strict liability principles: the duty to provide standard safety devices. The term "safety device" is used to apply to that class of articles which serves no functional purpose other than the protection of the reasonably foreseeable user (e.g. seat belts, locks, guards). The discussion is limited to those cases which deal with the extent of a manufacturer's duty to include a safety device, not those involving safety device effectiveness. Limited attention is given to whether the seller or the manufacturer is in a better position to anticipate foreseeable use; the focus is on the manufacturer's duty. It is concluded that if a product is inherently dangerous under all circumstances in the absence of an available safety device, justice demands that the device be incorporated as standard. If the product is dangerous only in the hands of a limited class of users or in a particular environment, logic suggests that the purchaser would be better able to anticipate such use and should have the burden of purchasing safety options made available by the manufacturer.

AUTO MANUFACTURERS AND HIGH SPEEDS: IS A FAST CAR A DEFECTIVE PRODUCT?

The question is explored whether common law liability should be imposed on the manufacturer of a car capable of excessive speed in cases where a person driving the car at such a speed injures a third party. The word "excessive" is used to describe the speed capacity beyond which liability for an accident resulting from speeding would attach to the manufacturer. The location of the point beyond which the speed is excessive would presumably reflect existing maximum posted speed limits, reasonable predictions as to future changes in those limits, data, energy consumption, and other relevant factors. The imposition of common law liability on the culpable manufacturer is examined, followed by the presentation of two alternative methods for imposing manufacturer liability: an act of Congress, and Federal administrative regulation. It is concluded that the manufacturer is as culpable as the speeding driver, and should be liable for the victim's injuries. If the courts fail to apply common law sanction, either the legislative or executive branch must act.

ROAD HYPNOSIS

Various forms of a phenomenon designated as "road hypnosi are described, as well as means to combat them. In some case drivers at night are hypnotized by the white lane stripes and a led off at the wrong exit. Other night driving situations involv a car backing up in the lane ahead but perceived by the a proaching driver as moving slowly in a forward direction. shifting within one's lane is called "box-in" or "sandwich" hy nosis, a form of claustrophobia. This occurs when the driver the center lane believes that the cars on either side are closin in on him. A similar form of "box-in" hypnosis involves th driver in the left lane next to a barrier/road divider in relatio to the car in the center lane. "Glare hypnosis" is the effect of a area on the pavement that appears wet and always moves wit the driver. "Giant hypnosis" involves the fear of being ove whelmed by a vehicle that is much larger than the affecte driver's vehicle. "Fatigue hypnosis" causes the field of driver alertness to become reduced becoming boxed-in to his own sel he begins to lose consciousness. Other forms of hypnosis a "windshield hypnosis," "straight line hypnosis" (continuing t drive straight when the road curves), "line hypnosis" (huggin the lane marker line), and "light hypnosis" (tendency to watc oncoming headlights).

PLASTICS: DETROIT'S PARTIAL REGIMEN FOR 'WEIGHT-CONSCIOUS,' GAS-GUZZLING AUTOS

The evolution of plastics technology in the U.S. auto industr began with the Ford Motor Co.'s development of a moldabl plastic sheet in the late 1930's. In 1971, the company displaye the country's first experimental plastic car body. In the earl 1950's several companies introduced limited-production sport cars with molded fiberglass bodies, one of which is still bein produced (the Chevrolet Corvette). Beginning in the mid-1950' vinyl upholstery became the first plastic material to be widel adopted for mass production by the auto industry. Corrosio protection and fuel economy improvements are the two impor tant factors in the use of plastics today. Of the nine material now used in cars, plastics rank third in total weight, toppe only by steel and iron. A considerable amount of plastic growth is expected, starting with the 1982 model year whe new body panels and structural components are approved. Th next areas of exploration include all-plastic windows, wheel and wheel covers, and fuel tanks. To the auto industry, plastic promise cost savings, weight reduction, energy conservatio and corrosion resistance. To the car buyer, they offer improve fuel economy, better design, and fewer maintenance problem

LEARNING TO LOVE THE PING [ENGINE KNOCK]

The most common cause of engine knock or pinging is the use of gasoline with an octane rating too low for the engine. The octane rating is simply a measure of the gasoline's ability to prevent knocking. The higher the compression ratio, the greater the efficiency of the engine, but also the greater tendency to knock. Refiners used to produce higher octane ratings by adding small amounts of knock-retardant chemicals, especially tetraethyl lead, but cars beginning with the 1975 models require unleaded gasoline because of their catalytic converters. Octane is designated as Research, Motor, or Research plus Motor divided by 2 (the rating required on gas pumps). Automakers believe that car owners should tolerate light, infrequent knock because it indicates maximum fuel economy from octane quality. Oil companies feel the same way, saying that a decrease in the octane rating of unleaded fuel nationwide could offer significant energy savings. Tips for the car owner in determining the lowest octane rating on which his car can run satisfactorily include learning to distinguish between minor pinging and damaging engine knock, having the car tuned, and checking the rating on the gas as it is bought and filling up successively with the next lower ratings if no knock occurs. Some general advice is that 1971-1974 model year cars should be able to use any grade of gasoline, cars built before the 1971 model year could develop problems with unleaded fuel, and 1975 models and later require unleaded fuel.

THE GREAT AUTOMOTIVE DEBATE

A perspective is provided on the debate between the U.S. auto industry and the Federal government. American and British statistics are compared in terms of vehicles-in-use, cars per population, annual mileage of the average car, and annual average fuel consumption. The current energy shortage is cited in the context of U.S. gasoline consumption. The evolution of legislation affecting the automotive industry is reviewed, starting with the National Traffic and Motor Vehicle Safety Act and the Highway Safety Act of 1966, followed by the Clean Air Act of 1970 (amended in 1977), and the Energy Policy and Conservation Act of 1975. The growth of the Federal regulatory system is described, including the rulemaking and enforcement activities of the National Hwy. Traffic Safety Administration. The efforts of the Center for Auto Safety, a public interest group, are discussed. The cost effects of meeting safety, fuel economy, and emission standards on the auto industry and customer alike are considered. There remains the question of the American car-buying public's response to the auto industry's large investment in downsizing programs to meet government fuel economy regulations.

ANY PROGRESS IN STOPPING? [CAR BRAKE DEVELOPMENTS].

Automotive brakes of today have two marked advantages over brakes of 20 years ago: they get rid of heat much more quickly, and they use linings whose frictional properties remain stable over a wide temperature range. No radical change is expected in the formulation of brake lining materials in the near future. The goal remains to produce a lining which will not wear out, which will apply a high frictional force for a low applying force, which will not grab on its initial application, and which will cause no brake squeal problems. The current trend is toward "harder" linings which wear better and remain more stable with temperature change, to give better fade resistance. The extra force needed to apply the brakes is provided by a servo. The brake designer has aided the lining manufacturer by designing brakes to keep temperatures at a tolerable level. For maintaining lower brake disc temperature, the best answer is to ventilate the disc by running air channels through the thicker part, or by simply making the disc bigger. Bigger-radius discs also reduce the braking effort required. More exotic solutions are water cooling and multiple discs of smaller diameter. Great advances are still being made in another brake component, the caliper assembly, not only in heat conduction but in design and contaminant protection. There is still no ready answer to the problem of brake squeal. Still to be realized is a practical system to store the energy created in braking in such a way that it could be used to reaccelerate the car. Much development work remains before antiskid brakes are generally available. Various brake systems are illustrated by drawings and photographs.

COMING: LIGHTER COMPONENTS [AUTOMOBILE CASTINGS AND FORGINGS]

Over the next few years, car castings and forgings will be reduced in size and weight, in some cases by materials substitution (e.g. aluminum or powdered steel for iron). Carbon and alloy-steel forge shops which make parts only for intermediate or full-size models are concerned about slumping sales in those segments, as are forge shops which make driveshaft and suspension components because of the trend toward front-wheel drive. The outlook for powdered-metal components seems brighter than for either iron castings or conventional steel forgings. Magnesium die castings are becoming competitive with those of zinc, and performance and durability of competitive plastic materials have also improved. Prospects of new automotive business for aluminum-casting companies are excellent. U.S. automakers plan to convert numerous components to the lighter cast aluminum over the next few years to meet stricter fuel economy standards. Iron castings will suffer more than other castings or forgings. Stainless steel is a potentially viable candidate for iron exhaust manifolds. Aluminum's cost, presently particularly sensitive, could strongly influence the auto industry's future materials programs. While the iron-castings content in cars is decreasing as aluminum castings increase, the forgings' iron content seems to be holding steady. Development of new, small, front-wheel-drive cars has eliminated some forgings, but has created demand for others. As more automotive components are reduced in size or redesigned to cut weight, the need for higher-strength forgings is likely to grow.

VENDOR QUALITY. THE HEAT IS ON [AUTO INDUSTRY]

Under heavy pressure from higher-quality foreign-car competition and burdened with service complaints and product defect and reliability litigation, the U.S. auto industry is demanding that its thousands of suppliers meet much stricter product standards. Each automaker has a program to extract higher-quality shipments from suppliers, resulting in expense to suppliers of hundreds of millions of dollars. The General Motors supplier quality control program is called SPEAR (Source Performance Evaluating and Reporting), a systems approach, incorporating representatives from each of the company's divisions who serve on quality teams that inspect and audit vendor quality. The basis for Ford's quality push is a recent revision of "Q-101," the company's Quality Control Specification. Chrysler's quality program is viewed as an extension of its own system. American Motors conducts quality audits of its vendors through its Supplier Quality Assurance Dept. Federal-Mogul Corp., a major industry supplier, has instituted a high-level quality council which selects audit teams that frequently tour the company's 25 U.S. plants to conduct critical evaluations, to make quality-improvement recommendations, and to ensure that they are put into effect.

EFFECTS OF PAVEMENT DELINEATION MARKING ON VEHICLE LATERAL POSITION-KEEPING

The effects of pavement marking and presence of other vehicles on the lateral positions of cars are reported for data collected by both fixed-site and moving-base observation techniques along suburban roads. Unobtrusive cameras were used for data collection to allow observations to be made on drivers who were unaware that they were being observed. The major dependent variable measured was lateral displacement of the car from the road centerline. The results of two studies indicate that there were reliable differences in the pattern of lane-keeping and lateral position between road sections that were similar in all respects except for the pavement delineation marking used. These data were also influenced by the presence of other vehicles. When drivers approach from opposite directions while in adjacent lanes, there is a systematic linear movement away from the road centerline which commences when the cars are separated in time by between 2.5 and 4 sec, and increases as the gap between the vehicles decreases. The time at which movement commences appears to depend on the delineation marking used. Use of direction indicators by drivers was shown to depend on whether lanes were defined by pavement marking.

AUTOMOBILE INSURANCE LOSSES, COLLISION COVERAGES; INITIAL RESULTS FOR 1979 MODELS

The collision coverage loss experience for car size groups, bo
style subgroups, and some individual vehicle series of 19
model year passenger cars during their first six months of ava
ability is described, based on data supplied by seven insure
(Aetna Life and Casualty, Allstate, Kemper, Nationwide, Pr
dential, State Farm, and Travelers). The initial collision cove
age losses for the 1979 models increased over the 1978 mod
year results from the same calendar period. The overall clai
frequency was unchanged but the overall average loss payme
and average loss payment per insured vehicle year increased
9%. Two of the four car size groups (subcompacts and co
pacts) had higher claim frequencies for the 1979 models than t
1978 models for the same calendar period and the other tw
size groups (intermediates and full size) had lower claim fr
quencies. All four size groups for 1979 models had higher ave
age loss payment amounts and three of the four had high
average loss payments per insured vehicle year than the 19
models. For the 1979 models, average loss payments per insure
vehicle year for three body style subgroups (regular two-do
models, regular four-door models, and sports or special
models) generally decreased with increasing wheelbase for su
compacts, compacts, and intermediates. In each car size grou
the average loss payments per insured vehicle year were highe
for the sports or specialty models and lowest for the regul
four-door models. Average loss payments per insured vehic
year, claim frequencies, and average loss payments per claim f
individual 1979 series varied considerably. There was more th
a fourfold variation in the range of average loss payments p
insured vehicle year. The claim frequencies varied by a fact
of more than two, and average loss payments per claim varie
from more than $1200 to less than $800. A list of other researc
reports by the Hwy. Data Loss Inst. is provided.

AUTOMOBILE INSURANCE LOSSES, INJURY COVERAGES; COMPARISONS OF CLAIM FREQUENCIES OF VOLKSWAGEN RABBITS WITH AUTOMATIC AND MANUAL SEAT BELTS, 1975, 1976, AND 1977 MODELS

The frequencies of insurance claims for injuries to occupants o
two groups of Volkswagen Rabbits, those with automatic be
systems and those with manual belt systems, are compared usin
"no-fault" personal injury protection and medical payments in
surance experience for three model years (1975, 1976, and 1977
Data were supplied by five insurers: Aetna Life and Casualty
Allstate, Liberty Mutual, Nationwide, and State Farm. Als
presented are the results of a survey of the medical informatio
in the injury claim files. Under the personal injury protectio

("no-fault") coverages, the VW Rabbits sold with automatic belts had slightly lower overall injury claim frequencies than those sold with manual belts. For the medical payments coverages, which are somewhat more limited, there were no discernible claim frequency differences between the two groups of cars. The results of the survey of the claim files indicate that in frontal crashes there were 17% fewer injuries to the occupants of VW Rabbits sold with automatic belts, and that the frequency of head injuries was 43% lower. In side and other crash types, the frequency of occupant injuries was about equal in the two groups. These results are important, since frontal crashes in general and head injuries in particular cause the majority of motor occupant deaths. A list of other research reports by the Hwy. Loss Data Inst. is provided.

HS-026 801

AUTOMOBILE INSURANCE LOSS, COLLISION COVERAGES; THE CONSISTENCY OF THE LOSS EXPERIENCE OF SPECIFIC VEHICLES PRODUCED IN SEVERAL YEARS, 1975 TO 1978 MODELS

The model year-to-model year consistency of the collision coverage loss experience results of specific compact and subcompact cars, 1975 to 1978 models, is documented, based on data supplied by eight insurers (Aetna Life and Casualty, Allstate, Kemper, Liberty Mutual, Nationwide, Prudential, State Farm, and Travelers). The collision loss experience of most specific cars remained consistently better, worse, or close to average regardless of the model year in which they were produced. Among both compacts and subcompacts, the relative rankings of cars in the same car size group, based on average loss payment per insured vehicle year, were essentially the same in each successive model year. The data show that if a car ranks better than another in its collision loss experience in one model year, most likely it will rank better in other model years. In each model year, individual four-door models generally had lower average loss payments per insured vehicle year, and hence ranked better, than the corresponding two-door model of the same kinds of vehicles. The relative claim frequencies and average loss payments per claim for individual cars were less variable across model years than the relative average loss payments per insured vehicle year. A list of other research reports by the Hwy. Loss Data Inst. is provided.

HOW OUR CARS DRIVE IN WINTER (GRAND TEST: COMMENT ROULENT NOS VOITURES EN HIVER) (GROSSER TEST: SO FAHREN SICH UNSERE AUTOS IM WINTER)

Results are presented for 26 foreign cars, typical of all makes and models, which were driven by the Country Touring Club of Kallis, Switzerland to evaluate their performance on the frozen, snow-covered Silser Lake and in the Albula Pass. All driving was done with steel-belted tires, and the cars were evaluated under normal and heavy loads. Each car was driven by ten drivers; their subjective evaluation and the elapsed time for completing the test courses were used to rank the cars. The superiority of front- vs. rear-wheel drive was demonstrated by a car's ability to negotiate curves on the frozen lake. The one rear-wheel drive car which was an exception was the Alfetta 1.8, a car with the gears located on the rear axle for optimum weight distribution of the axles. The mountain course was a curving, 1400 m road with a 170 m change in altitude, and grades up to 14%. Front-wheel-drive cars performed well when unloaded, but with luggage on board, they were unable to handle the steep grades. With a full load, only the Audi 100 LS and Citroen CX 2000 reached the top easily. Of the rear-wheel-drive cars, the Alfetta had no problems in the mountain test, whether empty or loaded. For the other rear-wheel-drive cars, the performance varied widely. The tests clearly demonstrated that an automatic transmission is very beneficial in mountain driving, particularly when starting up grades. Overall, on both the handling and mountain courses, the Audi 100, Alfetta, Fiat x 1/9, and Citroen CX performed well. The Volkswagen "bug", with rear engine and large wheels, was superior to many new designs. The following cars were less suited for winter driving: Ford Escort 1.3, Ford Taunus 196, Mercedes 280 SE (without automatic transmission), Opel Kadett 1.2, and Toyota Corolla 1200. The Range Rover, with four-wheel drive, was in a class by itself. Some winter driving tips are provided, such as, having good tires and brakes, and distributing passenger and luggage load appropriately.

REFLECTORIZED ROADWAY LININGS CUT HIGHWAY ACCIDENT, DEATH TOLLS

The pavement marking industry has made a considerable contribution to highway safety by developing fast-drying, highly-reflectorized marking materials, and equipment for their precise application. A pavement marking industry study together with Dept. of Transportation studies demonstrate the importance of proper roadway striping in terms of lives saved, injuries prevented, and economic losses avoided. Reflectorized edgelines alone can be expected to reduce accidents by more than 10%, and the addition of centerlines can effect at least a 20% reduction. Safety experts stress that roadway striping should be included in all highway/street programs with a goal of providing 100% lining; regular restriping schedules are also necessary. Striping equipment is now available to handle virtually any type of pavement marking assignment. Industry-conducted tests established that adding reflectorized centerlines and edgelines to 500 mi of Federal-aid and rural state secondary systems can prevent at least 3 deaths, 21 severe injuries, and 39 other injuries per year.

IMPACT ATTENUATORS SAVE LIVES, VEHICLES

To establish traffic flow together with safety during the replacement of a median strip on the Biloxi (Miss.) Bay Bridge, Con

Plex Corp. used two Truck Mounted Attenuators (TMA's) and one G-R-E-A-T CZ (Construction Zone Guardrail Energy Absorbing Terminal), both manufactured by Energy Absorption Systems, Inc. Also used were arrow signs, flagpersons, cones, and plastic channelizing sandbag-weighted reflectorized barrels. During construction work, the TMA's with their towing trucks were deployed on both sides of the median so that workers were protected from traffic (in the outer two lanes) in either direction. At the close of each workday, the G-R-E-A-T CZ impact attenuator was set up at the lead end of the newly poured section of median barrier. Con Plex reported that the portability of the energy-absorbing units enabled the company to use high-speed techniques and the overall nighttime safety made its procedures acceptable to the state. A reduction of two months in the original program time was realized. Crash cushions, or impact attenuators, have been making an increasingly important contribution to highway safety, according to the Dept. of Transportation. In addition to use on median barriers, they provide protection against obstructions in gores, massive sign supports, and bridge abutments. The Federal Hwy. Administration indicates that for every dollar spent on impact attenuators, the road users realize $123.80 in benefits. Other devices developed by Energy Absorption Systems include Hi-Dro Cushion, Hi-Dri Cushion, and Energite System attenuators.

HIGHWAY DEATHS SIGNAL 'EPIDEMIC'

The National Hwy. Traffic Safety Administration (NHTSA) reports 10,217 highway deaths from Jan through Mar 1979, the fatality rate running 14% ahead of 1978. Through May, the death toll was only 8% ahead, according to a Newhouse News Service report. According to NHTSA, the western and southwestern U.S. have fared the worst since 1975, indicating a 28% increase in traffic deaths; midwestern and southern figures went up by 10% and 7%, respectively; only the northeast rate was unchanged. NHTSA also reports an increase in fatalities per million miles between 1977 and 1978 for the first time since the 1966 safety program began. National Safety Council statistics list fatalities per million vehicle miles of travel for each state in 1978; they show Nevada with the highest percentage at 6.2, and the District of Columbia with the lowest at 1.7. Traffic Safety magazine reports that 16 states had decreases in fatalities during Jan and Feb 1979, with Alaska heading the list. A National Transportation Safety Board statistical comparison of 1977 and 1978 fatalities according to vehicle type indicates passenger car fatalities of 27,535 in 1977 and 28,120 in 1978. The Wyoming Hwy. Dept. credits various safety programs for the state's reduction in highway fatalities. Wisconsin transportation officials cite the disproportionate number of deaths among young drivers. The chairman of The Road Information Program relates the current decrease in highway deaths to the fuel crisis. Separate sections mention the efficient use of highway safety funds by the Iowa Dept. of Transportation, the lowest fatality rate in 20 years for 1978 on the New York State Thruway, and an increase of more than 20% for traffic accidents on Indian reservations in Arizona during 1978.

FORCES APPLIED TO A BICYCLE DURING NORMAL CYCLING

Forces that the bicyclist applies to the pedals, saddle, and han
dlebars during speeding, hill climbing, and starting were estimat
ed from cine film records using elementary mechanics. Th
results were compared with force measurements obtained fro
an instrumented pedal. Differences between estimated and mea
ured values of pedal loads were always less than 20%. It wa
estimated that a rider traveling at a steady speed of 37 kph o
level ground, and developing a tractive power of 255 W, exer
ed a maximum push on the pedal of 310 N, about 50% of h
body weight, and that about 50% of his weight was supporte
by the saddle. Toppling sideways was prevented by pulling u
one handlebar (71 N) and pushing down on the other (101 N
The maximum pedal load for a seated rider was recorded in a
indoor experiment when a power of 770 W was dissipated in
dynamometer. The maximum push applied to the pedals wa
then approximately equal to the rider's body weight (570 N
the maximum pull on the rear pedal being less than 100 N.
rider starting on level ground and accelerating at 2.6 m/sq s
was estimated to apply a force of 1448 N or more than twice h
body weight to the forward pedal and a pull of 367 N to t
rear pedal. The need to apply a large net pull on the handleba
and to counteract the large toppling moments produced by bo
pedals, in this case requires a pull of 714 N on one handleba
together with a push of 293 N. A rider climbing a one in t
incline at 26 kph, and developing a power output of 665 W, w
estimated to produce a maximum pedal force of 732 N, sligh
in excess of body weight. The pull on the rear pedal was ve
small and the net pull on the handlebars only 54 N, but the pu
on the handlebars was 235 N and the pull was 181 N. T
largest pedal forces recorded were for starting on an incli
when three riders each applied maximum pedal force of th
times body weight. Tilting the bicycle does not seem to of
great advantages.

DESIGN FOR ECONOMY [AUTOMOBILE ENGINES]

Future requirements for simpler and more efficient engi
could result in a return to long-stroke design to improve eng
economy. For a fairly wide range of engines, a standard form
expresses mechanical losses with reasonable accuracy: F
plus 0.15 N plus 0.05 N squared, where N is engine speed
1000 rpm. The slower running engine is likely to be m
economical. Using this formula, ways are suggested in wh
economy engine design should develop. The 1-liter engine
1985 is envisioned as being a transverse overhead valve, th
cylinder unit with a bore of 70 mm and a stroke of 86 mm
993 cc), hopefully developing somewhat more than 40 bh
4000 rpm, with good emissions performance. with a low ta
speed for peak power, combustion will have to be highly
cient. Part of that extra efficiency will have to be sought
higher compression ratio (CR). The answer to running eng
at higher CR'S on 95-octane fuel lies in electronic engine
trol systems. Engine design alone has the potential for a
saving in fuel consumption. Some engines are illustrated by
away drawings and photographs.

HS-026 809

REGULATORY IMPLICATIONS OF INDIVIDUAL REACTIONS TO ROAD TRAFFIC NOISE

Three categories of criteria for setting acceptable levels of road traffic noise are noise impacts (i.e. activity interference and effects on health), attitudes toward noise, and actions taken to reduce the impact of noise (e.g. complaints). The rationale for selecting criteria needs to be based on careful empirical analysis of two sets of relations: the relations among the plausible criteria, and the relations between the criteria and noise measurements. The first set of relations is examined by using questionnaire data collected at 37 sites adjacent to highways in southern Ontario, Canada. The results show significant but relatively weak links between impacts and attitudes and between attitudes and actions. The analysis results question the use of activity interference measures, and particularly speech interference, as a criterion for setting standards, and confirm the inadequacy of regulating against traffic noise on the basis of complaint action.

EFFECTIVENESS OF SHIELDING IN REDUCING ADVERSE IMPACTS OF HIGHWAY TRAFFIC NOISE

Some studies have suggested that the psychological effect of noise barriers or other forms of shielding between residential areas and noisy roadways is greater than their acoustical effect. This suggestion was tested by using home interview data from five pairs of residential sites in Ontario, Canada. The two sites that made up each pair experienced the same noise level at dwellings but had different types of shielding or barriers. It appears that there is no psychological effect on attitudes toward road traffic noise specifically, but that there is an effect for attitudes toward overall community noise. This psychological effect appears to be negative for solid noise barriers, low for single rows of trees, and highest for a row or rows of intervening housing.

HS-026 811

EFFECTS OF HIGHWAY NOISE ON RESIDENTIAL PROPERTY VALUES

Previous studies of highway noise have shown an effect on the price of housing that seems to vary considerably with location. In this analysis, six sites in Ontario, Canada, that consist of similar housing in parallel rows adjacent to major roads were identified, and data on real estate transactions and noise levels were collected. Analysis of variance indicated that there were significant differences in price between rows of houses only at the two noisiest sites. Consequently, multiple regression analysis was performed for two subsets of the sites based on noise level. The results show that at very noisy locations (daytime Leq (average sound level) of 73 dBA or higher) noise is strongly related to differences in housing prices and is valued at approximately $650/dB. At less noisy sites (daytime Leq less than 70 dBA), noise is not significantly related to differences in housing prices. These results suggest that some noise impacts are not a linear function of sound level, and that noise reduction at very noisy locations is more important than at less noisy ones.

HS-026 812

TEST OF SELF-STEERING TRAILER AXLES

In Ontario, Canada, self-steering trailer axles have found application by operators wanting to reduce tire wear of units with wide axle spread developed to take advantage of axle load regulations. By aligning with the turn, these axles can reduce both tire scrub and trailer offtracking. A test program was undertaken to ensure that these advantages are not achieved at the cost of reduced trailer stability and safety in steering and braking maneuvers at normal speeds. A triaxle van, equipped with two self-steering axle systems (one single axle, one bogie) was tested as a semitrailer in both low- and high-speed maneuvers, and compared with a conventional tractor-semitrailer. In low-speed cornering, both single axle and bogie self-steering systems reduced tire scrub. Bogie steering reduced trailer offtracking but the single axle (in its location as lead axle) did not. In high-speed braking and maneuvering tests (at speeds of 50 to 60 kph), one serious instability was observed. In a lane change with moderate braking, the lead wheels on the bogie locked up and slid. Under these conditions the bogie was unable to track behind the tractor but continued in the original lane. The manufacturer (Auto Steering Trailers, Ltd.) has a probable remedy for this problem. Single- and double-lane changes on wet asphalt (with and without braking) showed that the bogie system otherwise affected maximum maneuver speed by plus/minus 7%. Overall performance was slightly worse than with the bogie not steering. The single axle had a slightly beneficial effect, if any, on stability. Its potential as a replacement for a lift axle is not compromised.

WYOMING TRAFFIC ACCIDENT FACTS 1978

Traffic accident statistics for Wyoming in 1978 are compiled under the following sections: general statistics, where accidents occur, type of vehicles, type of accidents, seat belt usage, when accidents occur, driver and environment, drivers and casualties, teenage drivers, motorcycles, school buses, trucks, and city accidents. A spot map of fatal motor vehicle accidents is provided, as well as definitions of special terms used in the tables. The statistics were complied from reports submitted by individuals involved in accidents, investigating officers from city police departments, sheriff offices, and the Wyoming Hwy. Patrol. For the year 1978, a total of 17,775 accidents occurred on Wyoming's road system, a 15% increase over 1977. In these accidents, 7404 persons were injured and 241 persons killed (the fatal accident rate decreased 6.8%). Traffic accidents resulted in an $84 million economic loss (estimated by National Safety Council).

SELECTING TRANSMISSIONS FOR MOBILE EQUIPMENT

The energy crisis and higher operating costs are creating a demand for more refined transmissions in construction machinery, off-road trucks, and farm equipment. As a result, new powertrains weigh less, are more efficient, and draw upon the latest developments in technologies ranging from metallurgy to electronics. The function of the transmission is discussed, par-
ticularly matching engine torque to the torque demand
road and operating conditions. The most common trans
in mobile equipment are illustrated and described (manu
matic, powershift, and hydrostatic), as well as innova
transmissions (metal-belt drive, traction drive, hydrome
drive). The reduction of transmission component weig
stituting materials, use of stamped components), and th
computer modeling to optimize matching of powertrain
nents are considered. Greater interest is reported in
clutches for eliminating converter slip and in variable-
torque converters for making machines more versatile.
troduction of microprocessors into transmission control
prove accuracy and operating convenience is discussed.
static and electromechanical wheel drives in mobile eq
to provide design latitudes not possible with convention
are described and illustrated.

LIFE IN THE SLOW LINE [LINES AT GASOL STATIONS]

Photographs and their captions illustrate scenes reflecti
gasoline shortage and increased fuel prices in the U
lines at gas stations, cars being pushed or left by the si
road after running out of fuel, higher prices at the
stations permanently closed, no traffic on the highway
tisements selling recreational vehicles at bargain pri
people shopping for smaller cars. Some hints to help th
ist through 20- or 60-minute waits in the gas line inclu
about energy-saving measures (e.g. van pooling), make
ten new ways to save gas or concentrate on how to
trips for greater efficiency per gallon, use the tire
check tire pressures, consider the alternatives to waiting
line (e.g. carpooling), and mingle with fellow motorists.

CHILDHOOD ACCIDENTS. SUGGESTIONS MADE BY THE SWEDISH STATE COMMISSION FOR THE PREVENTION OF CHILDHOOD ACCIDENTS

The Swedish State Commission proposes the creation of a Child Safety Commission within the Dept. of Health and Social Welfare which would consist of representatives from the main political parties and from the five state authorities mainly involved in child safety issues (social welfare authorities, the schools, house planning, traffic security, and consumer safety). The central organization would be at the local level, with childhood safety advisers employed by the municipalities and paid by the government to coordinate accident-prevention activities. The State Commission also recommends a system for the registration of childhood accidents as an aid to the development of countermeasures. The Commission supports public education (via the mass media) to provide information on child development, accident risk, and preventive measures. The Commission also recommends the following: retroactive application of childhood safety rules in Swedish Building Regulations; means to eliminate dangerous products from the marketplace at an early stage; children under the age of 12 not to be held responsible for damages due to traffic accidents; implementation of efficient societal approaches to reduce fatal traffic accidents; accident prevention education as a part of regular schoolwork; stimulation of continued work by voluntary organizations to promote childhood safety; and promotion of active participation by parents and others to achieve a safer environment for children. The costs of these proposals would be 17 million Swedish crowns per year.

PEDESTRIAN ACCIDENTS

Among the predisposing factors of child pedestrians to accidents are the child's idiosyncratic understanding, inability to make complex judgments about distance and speed, inefficient peripheral vision and poor directional hearing, and lack of attention. Britain continues to have the highest rate of child pedestrian casualties in Europe, especially in the 5-9 age group. Safety education for children may not greatly affect their immediate safety but does lay a foundation for the future; the lessons need to be practical. In the protection of children from traffic accidents, the most important element is supervision. Children must also be given a safer environment, such as more protected or less dangerous play areas. Lowered speeds in residential areas (for example, by narrowing road width) would be beneficial. Drivers must be better educated about the behavior of child pedestrians, and their legal responsibility redefined so that the pedestrian has priority on certain residential roads. Emotional problems, physical ailments, incoordination, and lack of initiative are many factors making a child more accident-prone. Young and middle-aged adults are relatively safe pedestrains, unless they are drunk. Elderly pedestrians present problems similar to those of children. Vehicle design improvements such as energy-absorbing materials, "collapse" features, lower bumpers, and better hood design, can improve pedestrian protection. The pedestrian's interest must be given priority in city planning, exposure statistics are needed, and pedestrians themselves must behave responsibly.

HAZARDS TO CHILDREN IN TRAFFIC: A PAEDIATRICIAN LOOKS AT ROAD ACCIDENTS

The problem of road accident involvement of children is discussed in terms of mortality and morbidity statistics for the U.K., and the importance of child growth, development, and behavior as accident factors is addressed. The following statistics are tabulated and discussed· total and accidental deaths by age groups (1-4, 5-9, 10-14) and years (1951, 1966, 1971, 1974); total deaths from accidents, and road accident deaths by years (1967, 1976) for children; death rates (per 100,000 population) by social class in age groups, 1959-1963; and killed, seriously injured, and slightly injured children by road user type (pedestrian, cyclist, passenger in vehicle, driver or rider on motorcycle), England and Wales, 1976. Discussion of child development in terms of the traffic environment covers height, hearing, vision, divided concentration, right-left discrimination, and understanding of road signs and of words used in relation to traffic. Statistics are graphed and discussed concerning the sex differences of children aged 0 to 15 who were fatal and serious casualties in pedestrian and cycle accidents during 1973-1975, and risk per road crossing for boys and girls aged 5-10 years. The protection of children as passengers and pedestrians is addressed in terms of safer vehicle design, and use of child restraints, as well as the influence of bicycle design on cyclist accidents. In addition to driver, vehicle, and environmental factors, the role of the emotional and physical condition of a child pedestrian in accident causation is emphasized. The importance of developmental and psychosocial factors in childhood accidents, and the need for adults to know of children's limitations in traffic are stressed. The increased involvement of the pediatrician in this aspect of preventive medicine is strongly advocated.

SKANDIA REPORT 3. "UNPROTECTED ROAD USERS"

Using 1000 cases from the files of the Skandia Insurance Co. (Stockholm, Sweden) for the 1969-1970 period, an analysis was made, the first of its kind, of the particular problems of all age groups as "unprotected road users" (i.e. pedestrians, cyclists, moped riders). The behavior of each of the victims just before they became involved in the traffic accident was investigated. The conclusion from the analysis agrees with that of the first two Skandia reports (on traffic accidents involving children): that the high toll of traffic accidents is caused by lack of consideration by motorists to the road users' different ages and psychological ability to react. The motorist generally expects that all unprotected road users know the relevant rules for survival and apply them at all times. No consideration is given to their individual development or age, two factors which are critically important where children and the elderly are concerned (the two most affected age groups). Better traffic education is the essential foundation of a better traffic environment. Instruction should be given to all teachers and to day-care center personnel, special traffic instructor positions should be established at all schools, and driver education should include information on human behavior in traffic. Improvements in crosswalks could include setting signs about 20 m before the crosswalk, improving lighting, locating bus stops on the far side of intersections, and possibly using different kinds of crosswalk markings. A Traffic Psychology position at the university level is recommended.

RECENT DEVELOPMENTS IN THE FIELD OF ACCESSIBILITY TO THE BUILT ENVIRONMENT IN THE U.S.A. [BARRIERS TO THE HANDICAPPED]

The role of the U.S. in providing a barrier-free environment for handicapped persons is reviewed. Several State Handicapped or Accessibility Standards incorporate an holistic approach to design that ensures that solving one set of problems does not result in creating more problems for other people. With the 1973 Rehabilitation Act, the needs of most disabled people are beginning to be fully understood and changes are being made nationwide. By 1980, the law requires that schools, universities, and hospitals be fully accessible to all handicapped people including children. Most institutions have already evaluated their facilities in such terms. "Specifications for Making Buildings Accessible to the Handicapped" (American National Standards Inst. A117.1) have been under revision for nearly four years. Many states have meanwhile developed their own handicapped codes. Another Federal law (P.L. 94-147, 1975) requires a free, appropriate public education for all handicapped children. The new Federal and state laws address both the public and private sectors. While greater attention has been paid to buildings, the needs of the disabled in the exterior environment have gradually been brought into focus in recent years. Main problems faced by handicapped persons in the exterior environment include: systemwide mobility barriers (absence of usable pedestrian ways, inaccessible transportation system); inadequate component segments of the pedestrian system (e.g. time available to cross street, presence of rest areas); inadequate elements of the pedestrian system (ramps, handrails, surface materials), and other factors (turning traffic, crime, public awareness). The answer to these problems lies with a priority network of pedestrian routes connected to form a continuous system which can gradually be expanded, and interfacing with other accessible systems. The nature of districts must be analyzed and priority given to those used more by the elderly and handicapped.

HEALTH AND SOCIETY, 1. ACCIDENTS AND VIOLENT DEATH. CHILDHOOD ACCIDENTS

Historical trends in childhood mortality and accidental dea
rates in Sweden are discussed, including consideration of unr
liability or lack of data. To gain insight into the childhoo
accident picture, it is stated that reliance must be placed
special epidemiological studies. Four such childhood accide
surveys are reported, each conducted in a different area
Sweden. Various studies (particularly Swedish) on the involv
ment of children in road traffic accidents are reviewed: ch
dren's different reactions in traffic, the traffic environment a
accident causation, bicycle involvement, child restraints, a
residual symptoms among injured children. Studies of childho
drowning and poisoning accidents are also reviewed. The dif
culty in establishing a relationship among environmental hazar
accident proneness, adequacy of supervision, and safety educ
tion is addressed. Methodological problems in childhood ac
dent research are discussed: determination of exposure to ri
factors, selection (representativeness of data), inhomogeneo
result variable ("childhood accident" is not a single, unifor
concept; each accident type has its own epidemiology), the lo
frequency factor (difficulty in collecting enough data for ea
type of accident for a meaningful statistical analysis), equilib
um among accident factors (environment, accident pronene
supervision, education). Also discussed are determination of p
ventive measures, and Swedish laws for the protection of ch
dren against accidents. Media education campaigns and orga
zations concerned with the prevention of childhood accidents
Sweden are described. Some priorities for childhood accide
prevention include priority to accidents with high rish of seve
injury (e.g. road accidents, drowning), improvement of t
normal environment of children, education for all parents co
cerning hazards and improved collective supervision of ch
dren, and establishment of a form of simple, continuous registr
tion of childhood accidents. Research needs include in-dep
studies of accidents, and evaluation studies of countermeasur

THE TRAFFIC ENVIRONMENT OF PRESCHOOL CHILDREN IN SWEDEN

A survey of nearly 300 preschools in Sweden attended by a
proximately 100,000 children under six years of age was co
ducted by sending questionnaires to preschool personnel (
sponse rate of 95%) and to the children's parents (70%
sponse) to obtain information about the preschool traffic en
ronment and the child's mode of transportation and route t
from preschool. Time of year as well as the effect of prescho
geographical location were studied. A total of 19 accidents a
near-accidents was also studied for the Jan 1977 to May 19
period. For 15% and 25% of the preschools, respectively, t
traffic environment and the route to school were consider
hazardous. Dangerous traffic environment factors included la
ing or poor quality fences, lack of warning signs, obstruct
vision at entranceways, and excessive speed on roads around t
preschool. Lack of proper pedestrian and bicycle paths prese
ed safety problems for the large group of children walking a
bicycling to preschool. In nearly all of the preschools (96%),

least some traffic education was said to be given, although the form and extent varied greatly. Parents felt that most of the children's traffic education was provided at home. Nearly half of the parents used materials from "The Children's Traffic Club," a private organization active throughout Sweden in traffic safety education for children, providing "indoor" materials such as records and cutout materials, and some training exercises in actual traffic situations.

SEARCHLIGHT ON SAFETY [MOTORCYCLE HELMET USE]

A National Hwy. Traffic Safety Administration (NHTSA) study comparing the number of motorcycle fatalities resulting from head injuries pre- and post-repeal of mandatory helmet use laws in Colorado, Kansas, and South Dakota found that the number of such fatalities doubled after the repeal. Other NHTSA studies found that in states with mandatory helmet laws, the rate of compliance is very high (about 95%); after the laws are repealed, the rate decreases to below 60%. In all the states studied by NHTSA, the rate of head injuries increased after helmet law repeal. A study of motorcycle accidents in Illinois, which does not require helmet use, showed the motorcycle accidents resulted in three times as many serious or fatal head injuries as in Michigan, which has a mandatory helmet law. Subsequent to these various studies, NHTSA has requested the governors of repeal states to work for reenactment and those from states that have helmet laws to retain them. Each state has been asked to collect data on motorcycle helmet use and accidents involving head injuries and fatalities. The medical community, voluntary safety organizations, and citizen action groups have been made aware of the NHTSA report and have been asked to support helmet laws. Popular myths regarding helmet usage are refuted by facts from the NHTSA study.

ACCIDENTS INVOLVING HANDICAPPED DRIVERS

Background on the development of, and the use by handicapped drivers, of adaptive driving aids, and a review of the literature on driving by the handicapped (specifically accident involvement) are followed by a description of a study concerning the relative accident involvement of handicapped drivers, restricted to use of full hand controls, compared to other drivers. Using data from a driver population file of New York State drivers over 3 1/2 yr period, it was found that the handicapped drivers had a statistically significant higher accident rate (per driver) than nonhandicapped drivers. It was demonstrated that the accidents involving the full hand control group differed significantly from those involving other drivers by such accident variables as weather conditions, road system, and accident type. More data are needed on the relative driving exposures of the two groups. This study does not indicate that handicapped drivers using hand controls are necessarily more accident-prone than other drivers, but that they do have special driving problems. Handicapped persons need adequate equipment, training and driving experience to meet or exceed the safety records of other drivers. Recommendations for further research include studies of the performance of various mechanical assistive devices, a survey of the handicapped drivers in the present study, studies of the differences in various subgroups of the handicapped, and an examination of the question of state inspection of hand controls.

EMERGENCE OF THE "TENDER YEARS" DOCTRINE: TOO YOUNG TO DRINK, BUT CAPABLE OF ESCAPING THE CIVIL CONSEQUENCES?

A review is provided of judicial and legislative reaction (particularly in California) to pressures to extend the liability of the alcoholic-beverage vendor to his patron. California appellate courts have invariably rejected the liquor furnisher's civil liability for damages beyond the premises incurred by any patron, resulting from the latter's intoxication. A recent decision negated the use of comparative negligence to impose liability on the patron, at least in the case of adult plaintiffs. On 2 Jun 1977, a trial court's decision of first impression, holding that a tavern owner might be found liable to a minor patron, was denied appellate review on procedural grounds. The unreasonableness of the "tender years" rationale, which has been asserted to establish liability where none is generally believed to exist, is asserted in support of the conclusion that this class of minor plaintiffs cannot be permitted to benefit from its own wrongdoing. Potential defendents and their insurers must not bear the intolerable economic burden of assuming primary responsibility for consequences of drinking-related criminal conduct of minors, which often defies the law of self-preservation. Driving under the influence of alcohol demonstrates willful disregard for the minor's own safety. Holding the vendor liable for actions of minor patrons might encourage vendors to serve only adults, but vendor liability would encourage further disregard of the criminal law by minors engaged in drinking/driving. Stricter law enforcement, by way of criminal sanctions for both furnisher and consumer, rather than windfall civil recovery by the latter, is the most acceptable solution.

ACCIDENT FATALITIES, CANADA 1976

A series of comparative tables on accident fatalities (1975 vs 1976) is followed by detailed breakdowns of deaths in 1976 for each type of accident by age, sex, and province of Canada. Of the 167,009 deaths attributable to all causes in Canada in 1976 accidents accounted for 11,251 or 6.7%, down from 7.3% in 1975. The number of accident fatalities decreased by 1326 or 10.5%, and the rate per 100,000 population declined from 55.4 to 48.9. The ten leading classifications of accident fatalities, representing 94.6% of the total, were: motor vehicle (traffic), 45.4%; falls, 16.2%; drownings, 8.6%; fire, 6.8%; industrial type, 6.0%; poisoning 4.7%; suffocation, 4.3%; aircraft, 1.3%; firearms, 0.8%; and motor vehicles (nontraffic), 0.5%. Of the 5110 traffic fatalities, 76.6% were due to injuries sustained in three types of accident: collision with another vehicle, 1854 (36.3%); loss of control, 1199 (23.4%); and collision with pedestrian, 863 (16.9%). The 15-24 age group accounted for 1934 deaths or 37.8% and children under 15 years for 546 or 10.7%. The overall motor vehicle traffic fatality rate per 100,000 population decreased from 25.5 in 1975 to 22.2. For males, it decreased from 37.3 to 32.5; for females, from 14.1 to 12.0. Of the 863 pedestrian fatalities in motor vehicle accidents, 241 (27.9%) were children under 15, and 280 (32.4%) were persons over 55. Motor vehicle exhaust gas accounted for 86 of 127 deaths in the gas-vapor group. Of 62 motor vehicle (nontraffic) fatalitis, 16 involved children under 15. Next to motor vehicles, the home accounted for most of the fatal accidents.

FUEL FOR THE FUTURE. ANSWERS TO THE QUESTIONS ABOUT...CONVERTING YOUR CAR TO PROPANE

Questions commonly asked about modifying one's vehicle to use either propane or gasoline are answered, based on firsthand experience of the author who had a propane system installed in his car. The following aspects of propane conversion are covered: main reason for conversion, unlimited propane supply (price of propane 50 to 65 cents/gal as of Jun 1979); cost of system installation (about $1100 to $1200 in a car, about $800 in a pickup and about $300 for adaptation to new car), do-it-yourself installation (not advised); safety (exploding tank from rear impact or propane leakage in rollover accident unlikely with good equipment and correct installation); space taken up; operation on either gasoline or propane (including chance for fuels mixing); fewer emissions; better performance; no harmful engine effects; and illegality of installation in hatchback. Some of the disadvantages of propane conversion are also outlined: less fuel-efficient (decrease of 10% to 15%), unavailability of propane filling stations, restrictions from going through tunnels and over bridges, reduced trunk space, and limited travel range between stops because tank should be filled only 80%. Information is given on finding a dealer to install a propane system, including a list of propane-conversion shops. Photographs show an installed system.

HOW WE'LL RUN KILLER TRUCKS OFF THE ROADS

Fatalities in U.S. truck-related accidents increased consistently from 3483 in 1975 to 5120 in 1978. In 1978, the 191,837 new registrations of heavy trucks hit an all-time high, up 23% from 1977. On-the-spot investigations by the National Transportation Safety Board (NTSB) have found that many accidents result from mechanically deficient trucks and/or irresponsible operation. Of the 29,936 accidents in 1977 involving heavy trucks regulated by the Interstate Commerce Commission, 1650 involved trucks with mechanical defects; contributing to the remainder were truck or light-vehicle driver negligence, drinking, fatigue, and highway conditions. In one spot safety check in Pennsylvania in 1978, 382 out of 711 trucks were found in a hazardous condition. Since brake defects are the major culprit, NTSB urges construction of runaway "escape ramps" to avert brake-loss accidents on steep grades. The new Federal Motor Vehicle Safety Standard (FMVSS) 130 (revision of FMVSS 121) sets requirements in such areas as better resistance of truck brakes to heat buildup, a reasonable 60 mph stopping distance, and backup braking. Other National Hwy. Traffic Safety Administration proposals to reduce heavy-truck accidents include self-adjusting brakes for new trucks, better policing to get illegal/unsafe drivers off the road, stricter operating hours, speed-governing devices, installing tachographs, and underride barrier standards. The industry's self-regulation efforts are no substitute for the removal from the highway of incompetent and unsafe drivers, through government and industry cooperation. Some defensive driving tips for the motorist include keeping to the right lane, dropping speed and pulling close to shoulder on two-lane highways when a truck wants to pass, using lights to help trucks pass, being aware of potential runaways, and checking traffic before crossing signalized intersections.

ELECTRICS INFILTRATE THE RANKS OF LIFT TRUCKS

Industrial truck builders say that electric-powered lift trucks will soon overtake those powered by the traditional internal combustion machines, mainly because of rising fuel prices and impending Federal standards for vehicular noise. Electrics have virtually taken over the riderless vehicles; what remains is greater infiltration of rider-type machines (70% of the industrial truck business). The industry's leading builders of industrial trucks (Clark, Hyster, and Eaton) are increasing their manufacturing capability for high-volume production of electric lif trucks. Little change in the design of future lift trucks is anticipated by the industry, with steel continuing to be the most widely used material, chiefly for its inherent weight as a counterbalance to heavy lift loads. The design of electric trucks is limited by battery size. If a smaller-size battery with present-day performance is developed, some design changes may occur.

THE ELECTRICS ARE COMING

The Dept. of Transportation and The Dept. of Energy (DOE) are sponsoring the development of electric and hybrid vehicles, and foreign and domestic automakers are actively involved in electric vehicle (EV) research. The state of the art is centered around three vehicle classes: the all-electric, the hybrid, and the flywheel hybrid. All-electrics depend solely on the onboard storage batteries for power. Hybrids are of two types: an electric motor-driven system with some type of fuel-burning used to run a generator, and a more sophisticated hybrid concept that employs the fuel-burning engine to drive the vehicle in combination with the electric motor. The latest hybrid, under development by DOE, employs a flywheel to recover and store kinetic energy through regenerative braking. Most types of EV'S employ a regenerative braking system, whereby resistance caused by using the vehicle inertia to partially recharge the batteries aids in slowing down the vehicle. The lead/acid battery is still the best storage system, and the most promising new-generation system is the nickel/zinc battery which theoretically has twice the specific energy of lead/acid batteries. If cycling times can be increased and costs reduced, it could replace the present type. Metal/air batteries hold promise but are limited in peak power output. Zinc/chlorine hydrate batteries have theoretical specific energy about five times that of lead/acid systems, but supporting equipment is bulky. Molten-fuel sodium/sulfur batteries offer potential for extended cruising ranges, but present insulation and supporting equipment problems. To date, the greatest advance in EV development has been in the control system, now more much efficient. The goal is a 200-mi-plus range at highway operating speeds.

LITTLE CARS: THEIR TIME HAS COME

Little, economical cars envisioned for the near future U.S. market will be essentially two-passenger vehicles, with overall lengths of about 120 in and widths of about 50 in (compared to respective figures of 145.5 in and 59.3 in for a Honda Civic). These subcompacts will have gasoline or diesel engines ranging from 400 to 1000 cc, with hp ranging from 25 to 40. Engines and drivetrains will be at one end of the vehicle to help reduce weight and to allow for best interior space utilization. Luggage capacity will be very limited, intended mainly for carrying groceries, in line with the urban nature of the car's design. Fuel capacity will be about 6 gal, with mileage in the 60 to 80 mpg range. All cars must comply with Federal and state emissions and safety requirements. Lightweight metals and high-strength plastic will be used to keep vehicle weight down. The Japanese are the current world leaders in the development and manufacture of such high-mileage, miniature automobiles. Despite past failures in marketing tiny cars in the U.S., they will soon try again. The first of these might be the Subaru Rex 550, a four-passenger cruiser powered by a 544 cc, 4-cycle, 2-cylinder engine, with economy in the 60 mpg range. Another Japanese manufacturer, Mitsubishi, is a leader in emission control in small-displacement engines; it has recently applied its MCA-JET system to the 550 cc, 2-cylinder engine in its Minica Ami sedan. More than 25 years after the unfavorable U.S. reception of some small, fuel-efficient cars which were ahead of their time (e.g. the Nash Metropolitan, the Goggomobile Coupe De Ville (German), and the Citroen 2CV), the American public is faced with the choice of adapting to tiny cars or using public transportation.

MOBILE TELEPHONES: THE ULTIMATE AUTO ACCESSORY

Prospective buyers of mobile telephone systems are confronted with a wide array of hardware options. There is also the possibility of leasing phone equipment which can be operated under the lessor's Federal Communication Commission license. Leasing costs average between $75 and $90 per month, depending on whether the lessor is a private firm (radio common carrier) or the local telephone company. Leasing has the additional advantage of providing quicker access to a mobile-telephone number, for which there are long waiting lists. Prices for the mobile telephone begin at $1300 for a simplex (push to talk/release to listen) manual (place call through operator), with from 6 to 12 channels. Within the $1300 to $1800 range, there are a number of walkie-talkie or attache case phones which offer portability at the cost of reduced transmission/reception. "Real" mobile telephones begin at $1900 for a duplex (simultaneous talk/listen) direct-dial phone with a rebuilt transmitter/receiver box installed in the trunk. A brand-new, standard car telephone will cost $3000 plus $100 for installation, with optimal extra convenience features (e.g. channel scanning). Mobile-phone users pay monthly subscription fees ($12 to $18), regular toll charges, and air-time fees. Prudent users have monthly bills ranging from $40 to $60. It is noted that mobile telephone channels are shared, precluding confidentiality.

ON BECOMING GASOLHOLIC

Gasohol (one part ethanol, nine parts gasoline) is compatible with today's fuel systems, and produces minimal problems in unmodified engines, with minor emission, fuel economy, and performance effects. Gasohol can lead to slight start and driveability difficulties in some newer cars tuned to the lean limit for emissions control. It can increase fuel consumption by as much as 3%, but usually will have no effect. Gasohol reduces carbon monoxide emissions slightly, and may raise or lower hydrocarbons and nitrogen oxides. Although alcohol raises the fuel's octane rating (providing antiknock benefits), its volatility could result in poorer hot-weather driveability. The question of gasohol's net energy contribution remains to be answered. Even if ethanol conversion becomes extremely energy-efficient, if all the pilot production programs work (such as those being sponsored by the Dept. of Agriculture), and if there is enough damanged feedstock from which to distill ethanol, distilling capacity is a large obstacle to large-scale gasohol production. Turning the 100 billion gallons of gasoline used per annum in the U.S. into gasohol would require the production of 10 billion gallons of ethanol each year. At present, the ethanol-distilling capacity amounts to a mere fraction of that figure.

MAKING THE MILEAGE. THE ENGINEER'S DIET. PT. 2

Based on information provided by automotive engineers, a guide is presented to help the driver operate his car's engine efficiently. For carbureted engines, the key to good fuel economy is the carburetor. Driving for economy is mostly a matter of staying out of the power mixture (maximum power approaching full throttle when a power valve in the carburetor opens, substantially increasing fuel flow). Using a gauge for measuring intake-manifold vacuum (which triggers the power mixture), the throttle openings can be kept small enough to avoid the triggering point. The power-valve setting for an individual car can be obtained from the manufacturer's customer-relations department. For best mileage, operating in the area of maximum spark advance and keeping the revs down (i.e. getting into top gear as soon as possible) are recommended. For turbocharged gas engines, such as those in Buicks, the same operating rules apply as for their non-turbocharged counterparts (i.e. stay out of the power mixture if the extra performance is not needed). Fortunately, all turbocharged Buicks come with a manifold-pressure gauge in the form of a sequence of lights. For fuel-injected gas engines, recommendations for the D-Jetronic electronic system are to use a steady foot and to drive in the light-throttle range. For the L-Jetronic electronic and K-Jetronic mechanical systems with power-enrichment, the only fuel-economy action available for the driver is to use small throttle openings whenever possible. For all these Bosch injection systems, it is important to drive away as soon as the engine starts, and to avoid a lowering of the manifold vacuum (caused by tired spark plugs or leaking valves, for example). Diesels are the easiest to drive for economy; for best economy, low speed and constant fuel settings are recommended. It is possible to improve economy by eliminating emissions-control hardware, but the job is extremely complicated. To drive an electronic-spark-advance Chrysler for best economy, it is necessary to avoid closing the throttle as much as possible.

AGE AND BAC (BLOOD ALCOHOL CONCENTRATION) WHEN ARRESTED FOR DRUNKEN DRIVING AND PUBLIC DRUNKENNESS

Data collected from the arrest records of Randolph County in northeast Arkansas provided an opportunity to analyze the relationship between the age and the BAC (blood alcohol concentration) of persons arrested for alcohol-related offenses. BAC's of young people arrested for driving while intoxicated (DWI) and public drunkenness over a four-year period tended to be lower than those of older arrestees. The low number of offenders aged 25 or over with BAC's below 0.10% (0.09% the legal limit in Arkansas) is perhaps a consequence of older drinkers' having learned to compensate for the early effects of alcohol or having developed a repertoire of skills dealing with intoxication, including the ability to conceal or excuse minor behavioral aberrations. The large number of offenders aged 15-24 at BAC's below 0.10% is due to one or both of two factors: young persons are more likely to behave in such a way that police officers conclude that they are sufficiently intoxicated to be dangerous on the highways (even when they are not), or police officers find it convenient or desirable to arrest young persons who are not dangerously intoxicated. Novice drinkers can also experience "psychological intoxication" (i.e. abnormal excitement after drinking only a small amount of alcohol). Randolph County has been legally "dry" since 1953, and public sentiment against drinking is strong. The police department has been aggressive in its efforts to reduce drunk driving; nearly one-third of the incarcerations for each year between 1973 and 1976 was for DWI, three times the national rate.

THE INTERACTION BETWEEN ETHANOL AND ANTIHISTAMINES. 1: DEXCHLORPHENIRAMIN

Thirteen paid student volunteers (9 male, 4 female) participated in a double-blind crossover experiment to investigate the effects of a therapeutic dose of dexchlorpheniramine (DCPA) alone, and in combination with a social dose of ethanol (ethyl alcohol) on perceptual, cognitive, and motor functions. Both ethanol (0.75 g/kg) and the antihistamine (4 mg/70 kg) were given orally. Although a synergistic effect of DCPA with ethanol was observed in only some of the clinical tests, a delayed recovery from the effects of the combination was noted. Subjective evaluations indicated that the sedative effects of DCPA were more pronounced in the presence of alcohol.

POWER TAKE-OFFS FOR TRUCKS

Information is presented on pto's (power take-offs), which are basically gear-driven units that fit to, and derive their power from, the truck gearbox, transmitting that power through a drive shaft to the unit to be driven (e.g. winches, compressors, cranes). Categories of pto are described and illustrated: layshaft drives (including rear-mounted types), front-of-engine crankshaft-driven units, sandwich units between engine and gearbox, and split propeller shaft drives. Special adaptor gear assemblies, which have to be fitted to some gearboxes before attachment of pto's, are discussed, as well as speed change adaptors. Torque ratings are considered. The following aspects of the selection of a pto for a specific application are discussed: number of pto speeds, the direction of rotation of the equipment to be driven, output shaft hp and speed, gearbox capability, and type of gearbox. The installation of the pto and the driven unit for correct meshing is considered. Control systems are described, with special mention of the air shift. All truck and gearbox manufacturers are urged to pay more attention to the prospective needs of their users.

ROAD TRAFFIC ACCIDENTS: THE DOCTOR'S POINT OF VIEW

In a study of 135 road traffic accident admissions (38.8% of all accidents analyzed) classified by age, sex, and distribution of injuries, it was found that the adolescent and young adult males were mostly affected. The bed utilization rate in the wards where these accident victims were admitted was found to be lower than for other wards, possibly because head and neck injuries, which are the most common, have the highest fatality rate and may leave permanent residual disabilities. Ways by which the services in hospitals, both specialist and general, can be organized for a more economic and efficient care of road traffic accident casualties are discussed. Efficient on-the-spot first aid service should include organization and training of policemen, ambulance drivers and their crews in first aid. Experience has shown that with multiple casualties, attention should be given first to the quiet victims, who are often in more need than those who are actively complaining. The problem of sufficient beds in hospitals with many accident cases may be partially solved by improving the quality of accident care in peripheral hospitals, thus reducing the number of referrals. Also recommended are the training of physicians and surgeons in management of the acute phases of both head and spinal injuries; establishment of trauma services in all major general hospitals; a team approach to injured patients; and development of comprehensive regional accident services. Continued education in seminars and workshops would keep doctors up to date in management of the injured. In rural hospitals with only one doctor, the paramedical staff should be especially well trained. Minimizing disabilities with the purpose of successful rehabilitation should also be of concern. It is recommended that the doctor be a member of a National Motor Vehicle Safety Committee which is charged with the responsibility of approving the manufacture or importation of vehicles that meet basic safety requirements.

FUEL ECONOMY OF AUTOMOTIVE VEHICLES, A COMPENDIUM OF STATISTICAL TECHNIQUES

A series of nine working papers, chronologically sequenced, are the result of a study to develop a statistical methodology and to formulate specific statistical procedures for the analysis of in-use automobile fuel-economy data. The methodology developed addresses specific aspects of the following three issues: difference between actual, in-use gas mileage numbers and those reported in EPA (Environmental Protection Agency) certification tests; the reliability of EPA fuel-economy figures in providing a relative measure of gas mileage; and the tendency for the discrepancy between EPA and in-use gas-mileage figures to increase from one model year to another. To a considerable extent, however, the methodology represents adaptation of statistical techniques to generic questions which are not unique to the fuel-economy problem and can, accordingly, be construed in a much broader context. The topics covered by the working papers include upward bias of variance computed relative to the harmonic mean; bases for statistical estimation of fuel economy; estimating the standard error for a sample harmonic mean; considerations pertaining to the effect of accumulated odometer miles on mpg shortfalls; aggregation of data from sources with groups of "replicate" vehicles; philosophical and analytical issues affecting the Federal Energy Administration fuel-economy study; a regression/covariance analysis approach to estimation of fuel economy; some considerations affecting vehicle ranking according to fuel economy; and a regression approach to that ranking.

AUTOMOBILE INSURANCE--1978

Statistics on U.S. auto insurance business for 1978 (and 1975, 1976, and 1977 to indicate trends) are tabulated and discussed. Direct premiums, percentage of the total market, gain in premiums, loss ratio, and percentage of total premiums are given for leading automobile insurers, leading writers of private passenger auto insurance, and leading writers of commercial auto insurance. The percentage of the market share is estimated for national agency companies, regional companies, and direct writers (all auto business, and private passenger market); the trends in market shares are provided for the top 25 companies over the last four years. The total auto insurance premium distribution and leading writers by state are tabulated. In 1978, the direct premiums received by insurance companies for automobile coverages totaled $33.5 billion, a 9.9% increase over 1977. Private passenger liability premium volume (47.9% of the total auto business) gained 7% to reach $16 billion; the pure loss ratio rose 1.3 points to 64.7%. Commercial auto liability (13.5% of the total) was ahead 14.8%, reaching $4.5 billion; it gained nearly 4 points in loss ratio to 61.7%. Private passenger physical damage premiums (31.8% of the total) were $10.6 billion, a gain of 10.4%; the loss ratio was up more than 3 1/2 points to 65.2%. Commercial physical damage (6.9% of the total) showed an 18.7% gain in premiums to $2.3 billion; the loss ratio of 55.4% was 2.2 points above 1977. The emphasis on sales remained with the direct writers (a gain of more than 1/2 point in total market share); regional/specialty companies also increased, while the national companies lost a full point.

100-MILE RANGE CLAIMED FOR CITY EV (ELECTRIC VEHICLE)

Electric Test Vehicle-One (ETV-1), the first car to be built under the Dept. of Energy's (DOE) Near Term Electric Vehicle Program, was designed to have a driving range of 100 mi at speeds of up to 45 mph with two passengers (70 mi range in stop-and-go city driving with four passengers). The car will travel 115 mi at 35 mph constant speed. It has a cruising speed of 55 mph, passing speed of 60 mph, and the ability to climb a 5%, 1-mi grade at 50 mph. ETV-1 meets all Federal Motor Vehicle Safety Standards but one (glazing in side and hatch windows). It offers occupant protection in a 30 mph barrier crash. The electric vehicle is front-wheel driven by a separately excited dc motor, with transistorized choppers to control both armature and field power (newly designed by General Electric Co., the prime contractor). Batteries are an improved lead-acid type designed and fabricated by Globe Union, Inc., a major subcontractor. They have an energy density exceeding 17 Wh/lb and are expected to endure 500 deep-discharge cycles. Chrysler Corp., as another major subcontractor, had the responsibility for vehicle styling, body and chassis design, and vehicle fabrication. The car has 40% less aerodynamic drag than comparable subcompacts. With about the same exterior dimensions as Chevrolet's four-door Chevette, the ETV-1 is about 1300 lb. heavier (despite use of aluminum and high strength low alloy steel). A microprocessor in the power-conditioning unit manages power flow throughout the propulsion system. DOE says ETV-1 was designed as a practical car that could be mass produced for about $6400 (1979 dollars) by 1985. Life-cycle cost (10 yr lifespan) is estimated to be less than 18 cents/mi.

THE PROTECTION AFFORDED BY SEAT BELTS

The development of the seat belt is traced from early cumbersome designs through present automatic and passive restraint systems, with comments on the effects of each. Summaries are provided of eight selected European and U.S. accident studies concerning seat belt effectiveness in reducing or preventing injuries. Estimated reduction of serious injuries was found to vary from 45% to 70%. Seat belts were probably more effective in reducing the most serious injuries, particularly those to the head. Another study concluded that the wearing of seat belts by motorists in Victoria (Australia) reduced fatalities by at least 40%. Pre- and post-legislation wearing rates in Melbourne (Vic.) Australia, New Zealand, and some European countries are provided, and the wearing rates in Britain for five years up to 1977 are plotted. After the introduction of mandatory seat belt use legislation in Australia and New Zealand, for example, it was found that the percentages of car occupants wearing belts rose eventually to 80% or 90%. If legislation were to have the same effect on wearing rates in Great Britain, it is estimated that the annual decreases in fatalities and serious injuries, based on 1976 casualty figures, would be 630 and 12,900, respectively.

VEHICLE HANDLING: STEADY-STATE THEORY AND PRACTICE

It is demonstrated that simple two-dimensional steady-state handling theory will predict a vehicle's over- or under-steering characteristics. The terms "oversteer" and "understeer" can be defined mathematically and confirmed experimentally using the recommended method. It is shown that a vehicle's handling capability can be drastically changed by the mixing of tires; cornering stiffness for different tire sizes is compared. Among the tires tested, the steel radial was the "stiffest", followed by the textile radial and crossply. Experimental results from the handling tests are compared with simple theoretical predictions. It is easy to alter the basic characteristics of a vehicle, especially at high speeds, by combining unsuitable pairs of tires on t front and back; e.g., stiffer front tires than rear tires tend promote the oversteering condition. Handling characteristi can also be affected by tire pressures. To describe the behavi of a vehicle under all conditions is very complex, but by r stricting the theoretical approach to two degrees of freedo and considering only the steady state response, a much simpl fied mathematical model is derived which gives a satisfactor prediction of the vehicle's behavior.

SELECTION AND CONDITIONS FOR THE APPLICATION OF TIRES FOR UTILITY VEHICLES (AUSWAHL UND EINSATZBEDINGUNGEN VON NUTZFAHRZEUGREIFEN)

The criteria for selecting the appropriate types of tires fo commercial vehicles is discussed from the viewpoint of the development and availability. Developments leading to the stee belted radial tire are described and advantages of the radial ti enumerated. Tread patterns are illustrated; speed categories an classification by load capacity discussed. Selection criteria ar based on the vehicle design, dimensions, and use. Permissibl load per axle must be considered and a choice made betwee dual tires or special single tires. Extremes of temperature an difficult off-road conditions also require specially adapted tire Careful installation and attention to wheel alignment, tire pres sure and load are essential. Adjustment of load in a towe trailer is especially important. Driving habits, the way roads ar laid out, and conditions of road surface affect tire wear. In lon distance service, routine visual inspection of tire wear and possi ble damage are absolutely necessary. Prompt repairs may sav the tire and avoid safety hazard. Retreading must be performe competently and according to the manufacturer's instruction while at least 4 mm of tread depth remain. Appropriate storag of the tires, in a cool, dry, dark area, increases their service life It is predicted that full drop center tires (especially for the 20 and 16" wheel rims) with a cross-section ratio H/W (height width) 1 will remain on the market for a long time; but tire for tapered wheel rims with the standard H/W 0.85 (espe cially in sizes of 22.5" and 17.5") have many advantages an will eventually take over. To fulfill the requirements of com mercial vehicles, tires with a smaller H/W ratio will also b needed. Many new tread patterns, based on a wider flatte tread, will be needed to satisfy diverse requirements.

FUTURE AUTOMOTIVE TECHNOLOGY. A RESEARCH BLUEPRINT

A condensation, interpretation and amplification of the principal conclusions reached at the Boston meeting are presented. Three panels were organized, covering engines, fuel and powertrain systems, and vehicle structures and materials. The theme of the conference was basic research and the achievement of a fuller understanding of the physical and chemical processes underlying automotive vehicle technology. It was concluded that, through development and application of advanced technology, it is possible to achieve a total motor vehicle system with less dependence on imported petroleum than that legislatively mandated by the mid-1980's, while at the same time satisfying the implied requirements of safety, emissions and cost; some felt that a marketable 40 to 50 mpg automobile fleet is feasible by the year 2000. A well conceived and adequately funded program of basic research was urged, with the Federal government taking a leadership role. The recognized need for a capability to analyze the nation's automotive enterprise as a system led to recommendation of an Automotive Systems and Policy Analyses program. This would provide policy makers with the tools to examine all aspects of the automotive/energy system, would provide a guide for government and industry, and would aid in decision making on research priorities and resource investments, as well as energy and material conservation strategies and policies. A basic research agenda outline is suggested, including, besides the program just described, research on thermodynamics, combustion and fluid flow; structures; energy storage; engine/fuel interactions; materials science and processing; control systems; and friction and wear.

THE ROLE OF THE CITIZENS BAND RADIO SERVICE AND TRAVELERS INFORMATION STATIONS IN CIVIL PREPAREDNESS EMERGENCIES. FINAL REPORT

An assessment was made of the capabilities of the Citizens Band (CB) Radio Service (and other services in the Personal Radio Services) and of Travelers Information Stations (TIS) to provide emergency communications for civil preparedness operations. By a survey of state and local civil preparedness agencies, state police and highway patrol agencies, and volunteer CB organizations, the range of uses currently made of CB and TIS was determined. Among the formal organizations evaluated were REACT International, Inc., and ALERT Section, American Citizen Band Operators Association, Inc. The role of the Defense Civil Preparedness Agency in providing guidance in the use of CB and TIS in emergency situations was evaluated. Also evaluated were uses made of CB by truckstops, applications of CB by the National Weather Service SKYWARN program, impact of NHTSA National Emergency Action Radio program on emergency operations, and appropriate functional relationships between CB and amateur radio in emergency operations. The project found CB operators and their equipment, as well as TIS systems, valuable resources in emergency situations, and recommended a program to stimulate their effectiveness. Other specific recommendations encourage the use by state and local civil preparedness agencies of the CB Radio Service and the TIS. Appended are draft Civil Preparedness Circulars for CB and TIS, and a discussion of the impact of recent Federal Communications Commission Rules and Regulations changes on the effectiveness of the Radio Amateur Civil Emergency Service.

MECHANICAL BOOSTERS FOR BRAKE AND CLUTCH ACTUATION (MECHANISCHE VERSTARKER ZUR BREMSEN- UND KUPPLUNGSBETATIGUNG)

The systematology of various designs of mechanical boosters is described, with an explanation of which systems are suitable for today's needs and how to achieve optimum acceptance. Four categories of booster systems are studied: variable path ratio, adapted spring-assisted system, first-degree force dependence, and second-degree force dependence. Calculations of the maximum attainable amplification factor are included. It is concluded that, in contrast to pneumatically or hydraulically assisted boosters, mechanical force amplifiers demonstrate greater reliability and in many cases lower manufacturing costs. Photographs and diagrams illustrate the systems.

RELIABILITY OF PASSENGER CARS (ZUVERLASSIGKEIT VON PERSONENKRAFTWAGEN)

Trends are examined which emerged when comparing individual types of vehicles and their statistical data collected over a 8-year period by the Rhineland Industrial Monitoring Union in Cologne. Causes of vehicle damage may be design and fabrication defects, poor maintenance or improper operation, and wear and tear and aging. The defects most frequently appearing in vehicles over 6 years old are ranked in descending order: frames and supporting elements; parking brake on one side; low beam adjustment; engine and transmission leaks; front wheel suspension; exhaust system; foot brake on one side; headlight reflector; exhaust emission (high carbon monoxide reading); turn signals; tail lights and brake lights; tire tread depth; and steering mechanism. Analyses of these defects are presented. The number of defects in the wheel bearings remains constant at a low level, but testing methods should be improved. Data collecting of this kind should be very helpful to used-car buyers as well as to manufacturers. Special attention should be paid to the defects most frequently resulting in accidents, and the costs necessary to correct the defects found during periodic inspections must withstand a severe cost/effectiveness analysis.

COLLEGE STUDIES AUTO BODY REPAIR PROBLEMS

At an April 7, 1979, workshop at Bronx Community College, problems of the automotive industry were considered, in order to establish a college training program for automotive repairmen, bodymen, and transmission men. At the collision workshop, 29 people discussed their problems openly and freely. The difficulty of providing estimates on repairs was considered, with reference to the prevailing labor rate; repeal of the McCarran-Ferguson Act was urged. Dependence on insurance companies by the auto body shops was opposed; it was recommended that non-profitable jobs, where the insurance company dictated prices, should be refused, and that shop owners' standards should not be compromised.

IF WE CAN SEND A MAN TO THE MOON, WHY CAN'T WE RE-INVENT THE CAR? WHAT WILL THE CAR OF THE FUTURE LOOK LIKE?

Results are summarized of a two-day, three-panel conference to discuss basic research activities which could provide a pool of technological objectives for automobile manufacturers to develop and apply during the post-1985 period; the panels dealt with fuels and power trains, vehicle materials, and engines. Secretary of Transportation Brock Adams indicated that gasoline would continue to be the only fuel for many years; that the science community should not waste its efforts in trying to find alternative fuel sources. Objections were raised by several people who said they had already solved some of the problems being discussed, but because they had patents and would seek royalties, neither the government nor the major oil companies were interested in the solutions. Don Randall of the Automotive Service Councils felt that the conference should have addressed the problem of service, maintenance, and repairs, which comprise about 1/3 of the total dollar value of the industry. In a discussion of the appearance and construction of cars through the 1980's the question of collisions between cars of different sizes is considered, with the possibility of separate lanes for different sized vehicles. The future for auto body repair may include basic sub-assemblies, perhaps a throw-away section of the vehicle readily replaced with bolt-on components. Although new specialized techniques will be developed for auto body repai no better alternative than an auto body shop is likely to b available for repair of a crashed vehicle.

THE PARAMETERS THAT CONTROL THE PERFORMANCE OF THE IN-TANK FUEL STRAINER

As part of an investigation of the fundamental parameters controlling delivery of filtered fuel to the engine, the basic engineering factors required to understand how in-tank fuel strainers function are discussed. Guidance is provided for choosing fabrics that ensure optimum performance for various types of liquid fuels. The following major factors affect fuel strainer performance. The critical surface tension of the polymer must be less than the surface tension of any aqueous solution present in the fuel tank yet larger than the surface tension of the fuel. Water may be introduced at any point from the refinery up to the arrival of the tank truck, as well as by condensation in the fuel tank, and may dissolve sufficient material to provide a solution with a surface tension less than the surface energy of the polymer. Under these conditions, the "water" will wet the polymer surface. If the fuel wets the polymer surface, the fiber diameter need only be slightly larger than the width of the pores for the strainer to sustain fuel wicking. Water-fuel separation efficiency is best for very open fabric weaves, though this design would reduce the wicking capabilities of the strainer and make the strainer subject to water penetration as water is agitated by vehicular motion. The interdependence of performance upon pore size and fiber diameter means a compromise must be made after a review of the particular vehicle requirements. Uniformity of fabric weave, stiffness of the fibers, and resistance to fiber motion arising from interfacial forces are important requisites for a good fuel strainer fabric.

APPLICATION OF LASER DIAGNOSTICS TO AN INJECTED ENGINE

Measurements taken in a special, single cylinder, direct injection stratified-charge engine are presented. The optical measurement techniques employed include continuous-wave laser Raman spectroscopy for fuel and air concentrations, pulsed laser Raman spectroscopy for density fluctuations, high-speed cinematography for flow visualization, and laser Doppler velocimetry for velocities and turbulence intensities. More conventional data on cylinder pressure, power, and emission levels are also given. The study is designed to demonstrate the types of detailed measurements that are now possible within an engine cylinder.

A PULSED-ILLUMINATION, CLOSED-CIRCUIT TELEVISION SYSTEM FOR REAL-TIME VIEWING OF ENGINE COMBUSTION AND OBSERVED CYCLIC VARIATIONS

A closed-circuit television technique has been developed for the real time viewing and recording of combustion and related processes in internal combustion engines. The technique has been applied to a transparent piston, transparent head engine, where shadowgraphs of combustion chamber events have been observed and recorded. The technique is particularly suited for the study of changes in the combustion process due to variations of engine parameters such as mixture ratio, load, speed, spark timing, and injection initiation, since the changes can be observed and recorded as they occur. The key aspect of this television system which makes it applicable to rapidly varying events is the use of a solid state TV camera (Charge Injection Device) in conjunction with a pulsed laser light source which results in the charging of the camera sensor array in times of the order of microseconds. Included are diagrams of the components of the system, photographs of the system itself and the cyclic variation photographs it produces. A brief and qualitative study of flame and pressure cyclic variations is reported and discussed as an example of the particularly suitable application of the television technique.

LASER DOPPLER ANEMOMETER MEASUREMENTS IN AN INTERNAL COMBUSTION ENGINE

The capability of the Laser Doppler Anemometer (LDA) for making measurements inside a piston-engine cylinder is demonstrated. The backscatter mode of LDA operation was used, requiring only a single window in the cylinder. An ensemble-average data-processing technique was developed to analyze the raw velocity-crankangle data. Single-component measurements of mean velocity and rms velocity fluctuation at a single point are presented as functions of crankangle for three engine speeds. A comparison of motored and fired results is shown for one engine speed. Measurements of two components of velocity at several locations show the basic vortical nature of the flow field in this particular engine. Both the mean velocity and root mean squared velocity fluctuation appear to scale well with engine speed. The turbulence is generated primarily in the intake portion of the cycle and remains relatively uniform and constant during the compression stroke. Motored and firing results are quite similar until the time of ignition, and differ noticeably only when the flame is near the location of the velocity measurement.

FLOW VISUALIZATION STUDY OF THE INTAKE PROCESS OF AN INTERNAL COMBUSTION ENGINE

A water analog was used to visualize and study the generation of turbulence in a simple geometry cylinder during the induction stroke. The flow field, during the induction process, was observed to be structured and highly repeatable from cycle to cycle. The structure consisted of two ring vortices, of concentrated vorticity, which were of the same scale as the engine cylinder. A detailed study of the characteristics of the vortex rings was carried out for the case of an axisymmetric cylinder geometry. Inviscid scaling laws were obtained from these results that describe the development and stability of the structured flow field. Schematic diagrams, charts and photographs illustrate the process, including the effects of rpm, length of stroke and valve lift on vortex structure and the effect of valve seat angle on flow field.

GAS VELOCITY MEASUREMENTS OF A MOTORED AND FIRING ENGINE BY LASER ANEMOMETRY

The Laser Doppler Anemometer (LDA), a new instrument capable of making non-interfering gas velocity measurements, was used to investigate the gas behavior in the cylinder of a firing engine. The necessary conditions for a real-time measurement of the gas velocity were achieved by the LDA and thereby two typical flows, squish and torch, in the cylinder of an engine under both motoring and firing conditions were measured. As seeding particles for LDA which are applicable to gas flow within a firing engine, a soil powder for air-cleaner standard test (No. 8, JIS Z 8901-1974) was found to be adequate among a number of particles tested. Having seeded the flow, an LDA consisting of a fringe-mode optical system and a frequency tracking system was found capable of the time-resolved velocity measurements of gas flows in an engine operated under motored or firing conditions. Although the squish or reversed squish flow pattern calculated for the motored operation showed a good agreement with the observed one, substantial difference was found between the measurements for the motored and firing engines, particularly during the expansion stroke. The jet flow through a torch nozzle connecting the auxiliary and the main combustion chambers was measured and found identical to that calculated for the motored operation, but a distinct difference in the torch flow patterns was found between the motored and firing operations. The optical technique is shown to be applicable to research on a firing engine; these experimental results should be confirmed quantitatively by other instrumentation or theoretical estimations. Cross section diagrams illustrate the system.

USING MICROWAVES TO PHASE CYLINDER PRESSURE TO CRANKSHAFT POSITION

Improvments in transducers and data acquisition techniqu have provided increasing confidence in the magnitude of hig speed digital recorded cylinder pressure data. Techniques fo determining the correct phasing of these data with respect t crank angle have hitherto produced less reliable results. Bot amplitude and phasing are critical for determining such informa tion as indicated mean effective pressure (IMEP) and heat re lease rate in an engine cylinder. In some engines such as th direct-injection diesel, the IMEP must be accurate to 1%. new phasing technique is described which involves transmissio of microwave energy through the spark plug hole and into th cylinder of a motored engine. At certain piston positions, sym metric about minimum volume, microwave resonances occu These resonances are recorded on an oscilloscope screen alon with the one-degree pulses generated by the crankshaft. Analy sis of these recorded data yields pressure-crank angle phasin information accurate to the order of plus or minus 0.1 degre CA for open-chamber engines. Two production open-chambe gasoline engines and one divided-chamber diesel engine wer tested using this technique. A short computer program is give which aides the user in performing the required calculations t determine the pressure-crank angle phasing for a particular s of microwave data. It is noted that results of using the tech nique in a divided-chamber indirect-injection diesel engine wer disappointing, but it is believed that a modified technique woul improve this engine's probe response.

A DEVELOPMENT OF THE TRACTION ROLLER SYSTEM FOR A GAS TURBINE DRIVEN APU (AUXILIARY POWER UNIT)

A new type of speed reduction device was developed to driv an auxiliary power unit by a small gas turbine engine with speed of up to 86,000 rpm. The device features a traction driv system with planetary roller arrangement. In the traction driv system, power is transmitted by the tractive force generate between the rolling elements. The device has the potential t provide superior efficiency at a lower noise level over conver tional gear system, especially at a high rotating speed rang Transmission efficiency of 96% was evaluated for this unit at a input power of 22 kW. The evaluation was based on the frictio torque measured over the speed range of 50,000-65,000 rpm The major loss of this system was identified empirically as du to the sliding friction of the carrier. Further efforts to improv efficiency should be directed toward modification of the carrie configurations. It was concluded that excess oil supply in th race ways causes a considerable drop in torque capacity an increased churning loss in the traction system.

AIR BEARING DEVELOPMENT FOR A GM (GENERAL MOTORS) AUTOMOTIVE GAS TURBINE

General Motors' analytical and experimental programs are outlined for evaluating air bearing usage in vehicular gas turbines. Elimination of oil from the hot section of the engine, very low running losses and potential cost reductions are incentives to develop air bearings for the high speed rotors of automotive gas turbines. Low air bearing stiffness, start-stop wear and high starting torque are design challenges in this application. Air bearing operation was demonstrated in engine dynamometer tests. A better understanding of the many factors which affect the performance of cantilevered-leaf air bearings has been realized through extensive rotor dynamics rig testing coupled with development of bearing analysis computer programs. Measured running losses of the air bearing are much lower than those of the oil jet lubricated ball bearing it is replacing. Increasing leaf thickness, leaf-housing attachment angle, leaf free radius and eliminating the clearance between the leaf beam and housing slot increased the bearing stiffness.

CERAMICS IN ROLLING ELEMENT BEARINGS

The feasibility of using hot pressed silicon nitride (HPSN) for rolling elements and for races in ball bearings and roller bearings was explored. HPSN offers opportunities to alleviate many current bearing problems including DN and fatigue life limitations, lubricant and cooling system deficiencies and extreme environment demands. The history of ceramic bearings and the results of various element tests and bearing tests in rigs and in a turbine engine were reviewed. The advantages and problems associated with the use of HPSN in rolling element bearings are outlined. Among the advantages are low specific gravity, outstanding fatigue life, attractive lubrication (and non-lubrication) characteristics, low thermal conductivity, wide thermal stability range, low heat and noise generation, electrical nonconductivity, and excellent corrosion resistance. The problems in HPSN use include those of availability of material, machine ability for acceptable surface quality, quality measurement and control, and requirement for further information, such as load-life relationships, material characterization, and design modifications.

FOIL TYPE BEARINGS FOR THE CHRYSLER AUTOMOTIVE GAS TURBINE ENGINE PROGRAM--DEVELOPMENT AND OPERATIONAL EXPERIENCES

Oil-lubricated compliant foil bearings and rigid oil bearings were studied in comparison with an air-lubricated compliant foil bearing in a program to produce a gas turbine engine which would provide acceptable emissions, improved fuel economy, and competitive performance, reliability and manufacturing cost compared to conventional engines. Two years of testing have shown that the foil air bearing can meet load and temperature performance requirements. Work is continuing on extending operating life by improvements in foil bearing materials, welding, conformity, and surface coatings. The bearing has the potential for meeting the 1200 degrees F and low power loss needs of future engines. Areas for further investigation are outlined.

ASSESSMENT OF CURRENT U.S. DEPARTMENT OF TRANSPORTATION FIRE SAFETY EFFORTS. FINAL REPORT

In an assessment of transportation fire safety efforts, emphasis is placed on Federal government efforts, particularly those by the Dept. of Transportation (DOT). Pertinent information was gathered from a review of public and private sector fire safety programs related to transportation, data banks (materials and accident statistics), and regulations, standards, specifications, and guidelines. Government and industry efforts involved Urban Mass Transportation Administration, Federal Railroad Administration, Federal Aviation Administration, National Hwy. Traffic Safety Administration, Coast Guard, Office of the Secretary of Transportation, DOT Res. and Special Programs Administration, Federal Hwy. Administration, National Railroad Passenger Corp., National Bureau of Standards, National Aeronautics and Space Administration, National Fire Prevention and Control Administration, National Transportation Safety Board, American Public Transit Assoc., Union Internationale des Transports Publics, material manufacturers, and material users. Both material and statistical data bases were explored. Findings indicated that standards, guidelines, specifications, and recommendations differ considerably in terms of function and impact on the community. They are frequently misinterpreted and are sometimes erroneously used interchangeably. Appended are a bibliography of fire safety literature and a survey of DOT fire safety projects.

EFFECTIVENESS OF SPEED CONTROL SIGNS IN RURAL SCHOOL ZONES AND SMALL COMMUNITIES. FINAL REPORT

Experiments were conducted in Mississippi, California, and Oregon to test the effectiveness of speed control signs in rural school zones and small communities on high-speed two-lane highways. Test signs included existing signs, a "reduced speed ahead" sign, speed limit and "reduced speed ahead" signs coupled with hazard identification beacons, and a speed violation sign activated by a speeding driver. Roadside interviews were conducted, and a questionnaire was administered to determine the effectiveness of each sign in increasing safety and improving driver awareness of potential hazards. The questionnaire booklet provided information on public reaction to and understanding of signs. The combination of signs and hazard identification beacons and the speed violation sign provided the most substantial improvement in reducing speed and increasing awareness of roadside conditions for school zones and small communities. A wide variability in response to new signs persisted from site to site, the improvement ranging from 2-10 mph. The combination of signs was not always more effective than individual signs with hazard identification beacons. The speed violation sign, when added to signs with hazard identification beacons, resulted in no additional improvement at some sites. Signs without hazard identification beacons were inadequate in informing drivers of existing speed limits. Driver opinions indicated that effective speed control signs must be used in addition to the establishment of reasonable speed limits and strict enforcement in order to obtain a high degree of safety in rural school zones and small communities. The questionnaire booklet is appended.

THE EFFECTS OF "NO ACTION" NEGLIGENT OPERATOR HEARINGS AS AN ALTERNATIVE TO HEARINGS RESULTING IN PROBATION

A study evaluated the effectiveness of negligent operator hearings in which probation was replaced with the imposition of "no action". Of 6,489 California drivers who attended negligent operator hearings, 1,247 or 19% were considered high risk and were eliminated from the "no action" hearing program. The remaining 5,242 drivers were randomly assigned to either the group receiving license status as recommended (standard treatment) or the group with no action taken on their licenses (experimental treatment). There were no statistically significant driver record differences between the two groups 12 months prior or 12 months subsequent to treatment. The possiblility remains that removal of departmental actions from the individual hearing setting may have had a detrimental effect. Societal savings associated with the nonsignificant decrease in fatal and injury accidents for drivers in the "no action" group may result in a positive net financial impact for an implemented "no action" program. Analysis of low and high risk group characteristics suggests that the high-risk group did not have a higher accident expectancy than the nonhigh-risk group. Final program implementation recommendations are awaiting the outcome of a related study dealing with probation by mail (action without hearing vs. hearing without action). Procedural information and data are appended.

PASSIVE RESTRAINT SYSTEMS IN THE U.S.A. BASIS FOR THE DECISIONS OF THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION REACHED WHEN WORKING ON NEW LEGAL REGULATIONS (PASSIVE RUCKHALTESYSTEME IN DEN USA. ENTSCHEIDUNGSGRUNDLAGEN DER AMERIKANISCHEN VERKEHRSSICHERHEITSBEHORDE FUR NEUE GESETZLICHE REGELUNGEN)

Decision-making principles underlying the National Hwy. Traffic Safety Administration (NHTSA) action in introducing passive restraint systems are described from the perspective of automotive engineering, medicine, and economy, and their importance for the Federal Republic of Germany is assessed. The United States will gradually institue passive restraints for passenger cars in the early 1980's as a substitute for the obligatory use of safety belts. In contrast to so-called active restraint systems such as the safety belt, passive systems are designed to be automatically ready for use or automatically activated by special mechanical devices. Passive systems include impact cushions, passive safety belt systems which surround vehicle occupants, combined safety belt/knee cushion units, and air bags activated and inflated upon impact. The effectiveness of restraint systems for passenger car occupants in case of an accident is measured by their ability to prevent fatal injuries, diminish the severity of other injuries, or prevent all injuries. Passive restraint systems are not considered to be the safety equipment of the future in the Federal Republic of Germany, with the possible exception of the safety belt-knee cushion system. Possible adverse effects of air bags, and economic factors in the use of passive restraints are noted.

ETHANOL FROM BIOMASS AS AUTOMOTIVE FUEL (ATHANOL AUS BIOMASSE ALS KRAFTSTOFF FUR AUTOMOBILE)

The production of ethanol from biomass (foodstuffs and othe plants) is discussed as an alternative fuel. Of the nonpetroleum based alternative fuels under consideration in research project alcohols such as methanol and ethanol appear to offer the mos promising characteristics. Methanol represents the optimum so lution in countries with rich coal, natural gas, or woodlan resources and highly-developed industrial technology. Ethan is the fuel of the future in countries with dense vegetation and more agriculturally-oriented economy. The amount of biomas required to produce one liter of ethanol by fermentation an distillation ranges from 3-14 kg, depending on the type of biomass. Plants in Latin America and Africa (sugar cane, manioc, and milo), plants in the Federal Republic of West Germany (sugar beets), and the world harvest yield (rice, corn, grain, and potatoes) are examined in relation to the generation of ethanol from biomass. Economic and technological conditions that affect ethanol production are noted.

SYNFUELS: UNCERTAIN AND COSTLY FUEL OPTION

Technological processes involved in the generation of synthetic fuels are addressed in relation to President Carter's energy plan for the rapid development of fuels from domestic sources. The President has called for the establishment of an Energy Security Corp. to oversee the spending of $88 billion over a 12-year period, for promoting the production of fuels from domestic resources to replace 2.5 million barrels per day of imported petroleum. Most Federal funds have been channeled to coal conversion projects, because coal is the most abundant fossil fuel resource in the United State and coal conversion technology is more advanced than other synthetic fuel techology. A leading contender in coal gasification competition is the German-developed Lurgi gasifier which employs a pressurized fixed-bed reactor and works well with noncaking coal like that found in North Dakota and western United States. The Koppers-Totzek gasifier, an entrained-bed reactor operating at atmospheric pressure, can be used with almost any type of coal. The Winkler gasifier is a fluidized-bed device that operates at atmospheric pressure. Several projects supported by the Dept. of Energy include a fluidized bed process, "Hygas", developed at the Inst. of Gas Techology, "Synthane", developed by the Bureau of Mines, and the Texaco gasifier where coal is pumped in as an aqueous slurry and gasification takes place in a high-pressure concurrent reactor with ash discharged as slag. Coal can be transformed into liquid fuels by pyrolysis or by indirect and direct hydroliquefaction. Shale oil and coal liquid are deficient in hydrogen and require considerable upgrading (including severe hydrotreating) to be suitable feedstocks for conventional refineries. From a testing standpoint, the most advanced surface retorting processes in the United States are Oil Shale Co.'s TOSCO II process, Union Oil's steam gas recirculation process, and Development Engineering's Parahoe process. In-situ shale processing technology developed by Occidental is reported, potential sources of synthetic fuels are noted, and cost and environmental impacts of synthetic fuel technology are considered.

OPERATION LIFESAVER: A PROGRAM TO REDUCE ACCIDENTS AND DEATHS AT RAILROAD-HIGHWAY CROSSINGS

The Operation Lifesaver program, developed by the Union Pacific Railroad to reduce fatalities at railroad-highway crossings, is described. In the typical railroad-highway accident, a motorist driving at a moderate speed (usually less than 25 mph) is involved even if the warning device at the crossing is properly functioning. Operation Lifesaver programs implemented in Idaho, Nebraska, Alabama, Georgia, Kansas, Missouri, and Utah have reduced fatalities by 28% to 64%. Operation Lifesaver has been recommended for nationwide adoption by the National Transportation Safety Board. It is based on education of the general public, enforcement of safety laws, engineering improvements, and evaluation of progress with regard to effectiveness and continuity. Planning for the nationwide effort has involved the cooperation of government and private sector organizations. Operation Lifesaver has been endorsed as a priority concern by the National Assoc. of Women Hwy. Safety Leaders, American Driver and Traffic Safety Education Assoc., Assoc. of American Railroads, Federal Hwy. Administration, Federal Railroad Administration, National Hwy. Traffic Safety Administration, National School Transportation Assoc., and the Department of Transportation. As the result of planning efforts, California and North Carolina have initiated Operation Lifesaver programs and 14 more states have expressed interest.

MULTIPIECE VS SINGLE PIECE WHEELS. THERE ARE RISKS WITH TRUCK TIRES BUT...

Testimony was presented by Philip M. Besuner, a representative of a California consulting firm before an Occupational Safety and Health Administration (OSHA) hearing panel dealing with multipiece tire wheels. Effective promulgation of proposed OSHA standards can potentially prevent 68% of accidents and 84% of fatalities associated with multipiece wheels. The cost of implementing the standards appears insignificant to moderate and therefore more cost-effective than multipiece rim replacement with single-piece rims. The cost of replacing multipiece rim components is unjustified due to lack of evidence that a change in rim type will reduce the small rate of fatalities. Risk posed to society by the multipiece rim is so low that a factor-of-three increase in the number of known accidents will not significantly affect the validity of this conclusion. Most risk related to using multipiece rims is centered around maintenance activities. Eighty percent of mishaps occur during maintenance and the fatality rate for these mishaps exceeds the moving vehicle fatality rate by three times. Recognizing that maintenance tire specialists are exposed to the risk of wheel-related mishaps for periods of about 20 or 30 minutes per wheel in maintenance and only 20% of mishaps are fatal, their exposure to risk (per tire change or per unit time) is less than the risk accepted when they drive to work or travel on commercial aircraft. Any safety-intended replacement of multipiece wheels with single-piece wheels should be implemented only when a substantial decrement in risk can be shown, sufficient to offset the resulting cost and disruption. Single-piece rims suffer from tire bead explosions that virtually never occur on multipiece rims, but side rings of single-piece rims do not exposively separate. Costs per forestalled fatality of various highway safety measures are compared with those of mandating single-piece rims (from $506 to $5.8 million vs $125 million). Procedures to follow in minimizing the risk of injury associated with explosive separation are identified.

CHILD AUTO RESTRAINT DESIGN PRINCIPLES

Anatomical considerations and general principles of occupant restraint in the car crash environment are explored, with emphasis on the protection of children, and design criteria and typical performance problem areas in child restraint systems are discussed. A major problem in the design of necessary special restraint systems for children is that of providing a device compatible with a child's size and anatomical features. Overriding criteria for child seat designs relate to their crashworthiness, specifically involving structural integrity, dynamic interaction with the adult seat, proper use of adult restraints to secure the child seat and load distribution, as well as considerations of limitation of body motions, comfort, usability, and cost. Many prototype systems which apply the preceding restraint criteria fail to anticipate the magnitude of loads produced in a typical dynamic crash test and the effect of loads on the seat structure. Common problems with prototype designs are structural collapse and rupture, concentrated loading of the occupant, and high occupant accelerations due to harness and padding inadequacies. The capability to design and manufacture effective and practical child restraint systems is reflected in some systems available on the market. Child restraint provisions embodied in Federal Motor Vehicle Safety Standard 213 are not effective in eliminating structurally deficient systems from use. A dynamic test procedure is needed to produce the appropriate type of loading for restraint system evaluation. Revisions to Standard 213 should reflect real world conditions in test crash pulse severity and direction, and should provide effective but not overly restrictive performance criteria, promotion of widespread usage, and cost-effectiveness.

ROAD CURVE GEOMETRY AND DRIVER BEHAVIOUR

The development of design policies for the horizontal alignment of road curves is viewed from a historical perspective, and empirical studies of driver-vehicle behavior on road curves are examined. Particular consideration is given to assumptions made about vehicle speeds, to criteria for determining safe speeds on highway and intersection curves, to the super-elevation associated with different degrees of curvature, and to criteria for effecting transitions in curvature, super-elevation, and pavement width. It is suggested that adoption of the assumed design speed concept in the mid-1930's diverted attention away from study of the actual behavior of drivers on road curves and distorted the investigation of such questions as safe speed super-elevation/curvature relationships. Literature on empirical observations of driver-vehicle behavior on both highway and intersection curves is critically reviewed. Evidence of deviations from the idealized behavior assumed in current design policies is pointed out, and several previous interpretations of data are criticized. Necessary research is outlined.

COMPULSORY BLOOD ALCOHOL TESTING OF ROAD CRASH CASUALTIES IN VICTORIA [AUSTRALIA]: THE FIRST THREE YEARS

The history, rationale, and implementation of legislation for compulsory blood alcohol tests for adult road crash casualties brought to Victoria (Australia) hospitals are reviewed. The legislation permits drinking drivers admitted to casualty departments to be identified and prosecuted, and physicians can obtain blood alcohol test results for road crash casualties without the threat of litigation. Drinking drivers and nondriver casualties with alcohol problems can be directed to appropriate re-education or rehabilitation programs (compulsory for drinking drivers). In the first three years of testing, 27.1% of 21,863 male driver casualties had blood alcohol concentrations (BAC's) over the legal limit of 0.05g/100mL, and 13.7% had BAC's over 0.15g/100mL. BAC's in 8.7% of 9,187 female driver casualties exceeded 0.05g/100mL; 3.7% of these drivers had BAC's over 0.15g/100mL. Nondrivers had a slightly lower incidence of elevated BAC's. Implementation of further drink-driving countermeasures, expansion of services for managing alcohol problems, and development of a national policy directed at preventing alcohol abuse are recommended.

THE EFFECT OF THE ABSOLUTE SPEED LIMIT OF 100 KM/H ON ACCIDENTS IN VICTORIA [AUSTRALIA]. TECHNICAL REPORT

Accident, injury, and speed data collected in Victoria, Australia, were analyzed to determine the effectiveness of the 100km/h rural speed limit in reducing the number of road accidents and persons killed or injured. Free speed data were obtained by the Road Safety and Traffic Authority at 12 sites from 1972 through 1976. Analysis of data suggested that a lower proportion of vehicles exceeded 100 km/hr areawide with the introduction of the reduced absolute speed limit in 1974. Throughou 1975-1976, however, this proportion increased. Adverse weather and seasonal effects may have affected some results, the latter being of particular importance when comparing speed measurements in 1973-1974. The general trend in reported casualties was toward a decrease in 1974 and a subsequent increase in 1975 for high and low speed zones. The incidence of single-vehicle accidents may have been more affected by changes in trave speed than that of multivehicle accidents. Largest percentage decreases for single-vehicle and multi-vehicle accident types in 1974 occurred on high speed zones of divided highways. The ratio, vehicle occupants killed plus injured admitted to hospitals/ vehicle occupants involved, was calculated for the 1973-1975 period as a means of assessing changes in personal injury severity. Contrary to expectation, there was an increase in the ratio over the 3-year period for high and low speed zones. In general, no causal link between vehicle free speed and accident occurrence could be established. Supporting tables and figures are provided. Information relevant to seasonal influences on free speed measurements is appended.

1978 TRAFFIC ACCIDENT FACTS: AN ILLUSTRATED ANALYSIS OF ACCIDENT RECORDS [FLORIDA]

Detailed data on traffic accidents in Florida during 1978 are tabulated. There were 326,199 traffic accidents involving 596,423 drivers; 183,324 persons were killed or injured in 116,880 accidents and 2,085 fatal accidents claimed the lives of 2,305 persons. Pedestrians comprised 3% of all persons injured and 24% of all persons killed in traffic accidents. The 1978 mileage death rate of 3.2 deaths per 100 million vehicle miles of travel represented the first increase in three years. Of pedestrians killed, 20% were not crossing at intersections or crosswalks. More than two-thirds of all persons killed, 64% of all drivers in accidents, and 78% of all drivers in fatal accidents were males. Fatalities increased by 12% from 1977 to 1978 and accidents increased by 14%. Although 64% of all accidents occurred in urban areas, 61% of all traffic deaths occurred in rural areas. The ratio of injured to killed was 79:1. Seat belts were available in 88% of all motor vehicles involved in accidents, but only 14% were in use at the time of accidents. Of 1,295 persons killed who had seat belts available, only 6% were using them.

SAVING FUEL WITH TRUCK DRAG-REDUCTION DEVICES (ECONOMIES DE COMBUSTIBLE AVEC DES ACCESSOIRES AERODYNAMIQUES POUR CAMIONS)

Actual on-road and wind tunnel evaluation work carried out by Transport Canada to estimate fuel savings and benefits associated with the use of truck drag reduction devices is reported. The primary source of aerodynamic drag on trucks is a pressure force caused by the impact of air on the front of a moving vehicle. A cab-mounted drag reduction device deflects air at an angle over the trailer or van body projecting above the cab. Skin drag, caused by friction between air and vehicle sides, is less significant. In addition to cab-mounted drag reduction devices, there are trailer/van-mounted devices and cab/van gap-mounted devices. Fuel savings attributable to drag reduction equipment are related to vehicle load. It is recommended that users request manufacturer data on the basis of gallons of fuel saved per 100 miles rather than on percentage gains. Guidelines are offered to facilitate the selection of a drag reduction device, to maximize fuel savings, and to check the performance of a particular device under fleet conditions. Factors affecting fuel economy are noted, including wind conditions, vehicle load, differences in performance of unequipped vehicles, driver habits, and traffic conditions.

CRASH PROTECTION FOR CHILDREN AFTER THEIR THIRD BIRTHDAY

Ways of improving the use of child restraints after 3 years of age, by developing more acceptable devices, are examined. Intended as a guide for use by administrators, manufacturers, and others, the report covers the selection of protective devices for children (chairs with harnesses, child harnesses, belts designed for adults, booster cushions, and cushions and chaises). Any child restraint should be adjusted to have a minimum slack. Retractors are extremely beneficial in reducing slack. Laboratory testing indicates that booster cushions are satisfactory if they can be restrained in crashes by the child's weight or by suitable anchoring devices. The use of booster cushions with child harnesses or seat belts greatly increases their acceptability. Legal requirements for child restraints are discussed. Narrative, tabular, and graphical information on various child restraints, including booster cushions, is appended.

CHILD RESTRAINT FIELD STUDY (PROJECT REPORT ON "IMPACT-3")

An in-depth study of 149 children, aged less than 8 years, who were ostensibly restrained in preparation for crashes, and who actually experienced collisions while traveling in passenger cars, is presented. Crashes occurring within an 80-km radius of the center of Sydney, Australia between Jan 1974 and May 1975 are included. The speed limit was 60 km/hr or less at the scene of 106 (87%) of the crashes. Collision forces were from the frontal direction in 56 (46%) of the crashes. Vehicle damage intruded into the occupant compartment in 57 (47%) of 122 case vehicles and the vehicle overturned in 10 (8%) of the crashes. Most study participants (58%) were less than three years old, and about two-thirds of the sample were traveling in the rear seat. *At least 37 case occupants* were ejected from their restraints, or had them detach from the vehicle, and four occupants were ejected from the vehicle. Most child restraints involved in the accidents were not approved by the Standards Assoc. of Australia. Children in restraints approved by this association received nothing worse than minor injury. Similiarly, restrained bassinets gave moderate protection. Seat belts supplied for adults tended to be worn very loosely by children and, in that condition, did not provide adequate restraint. Most injuries were to the head following contact with car interiors. Recommendations to improve crash protection for children are offered. Appendixes note cases involving moderate injury or worse, cases involving large vehicle deformation ratings, and types of child restraint devices.

ENEL (ITALIAN ELECTRICITY BOARD) EXPERIENCE AND DEMONSTRATION PROGRAMS IN THE FIELD OF ELECTRIC VEHICLES

The Italian Electricity Board's program of research, development, and demonstration to explore the use of electric vehicles is examined. The program includes general studies to evaluate the potential of electric vehicles in various areas of road transport in relation to 1980-1990 technological developments; study of the development of electric vehicles and related components for specific application to urban-suburban areas; and study of infrastructures necessary for large-scale urban-suburban use of electric vehicles. Emphasis is placed on the near-term application of electric vehicles, Board actions relevant to the development of city vans, Board demonstration programs on electric van fleets, and Board methods and instrumentation for tests on electric vehicles and their components. It is envisioned that widespread use of electric vehicles will be beneficial for the energy situation and the environment, and that overnight battery recharging will contribute to balancing the electric load profile. Laboratory and on-the-road tests are planned by the Board to improve vehicle and battery performance. Photographs and specifications are provided for electric vehicles under study.

THE LONDON ELECTRIC DELIVERY VAN ASSESSMENT SCHEME

Performance, reliability, and maintenance and running costs of 62 battery electric delivery vans, supplied by three manufacturers and used daily in the Greater London area, are being assessed over a 3-year period to compare their operation with closely equivalent conventional vehicles. The primary purpose is to obtain independent operational experience covering a wide variety of suitable applications over an extended period and to provide reliable factual information about the performance of electric vehicles in normal daily use with typical drivers and loads. Significant elements of the London electric delivery van assessment scheme are monitoring, collection of daily operating data, consideration of vehicle maintenance work and downtime, and establishment of the scheme's scientific validity. Results of vehicle assessment are to be presented in a separate paper.

HELMET SUPPORTER SEES FLAWS IN OBJECTIONS

An article dealing with motorcycle helmet use, "Easy Rider -- Hard Facts: Motorcycle Helmet Laws," by Pearl K. Russo (New England J. of Medicine) is reviewed. Facts are gathered from a number of studies that support the use of motorcycle helmets as a safety measure. Helmets in one form or another have been used as protective devices for thousands of years. According to a British study, with increased use of helmets in the 1960's, the fatality rate from accidents involving head injuries dropped about 50%. A 1970 study in Sacramento, Calif., based on police reports, death certificates, and hospital records, supports the value of helmets in saving lives. Four objections to helmet use are refuted: helmets increase the risk of neck injuries; helmets reduce the cyclist's peripheral vision, thereby creating a hazard; helmets reduce the cyclist's ability to hear other vehicles in traffic; and helmet weight increases rider fatigue, thus causing accidents. The constitutionality of helmet use laws is considered, along with societal costs of motorcycle injuries.

TRUCK ESCAPE RAMPS: EXITS TO SAFETY

The design of truck escape ramps is addressed, with reference to the construction of ramps in Colorado, Oregon, Idaho, Washington, Utah, New Mexico, Texas, California, Virginia, West Virginia, Pennsylvania, North Carolina and Tennessee. Highway departments in many parts of the country are building ramps at key locations where truck drivers have been killed i run-off-the-road crashes. Most ramps follow a similar desig pattern. Signs on a downgrade alert drivers of trucks wit failing brakes to a strip of loose gravel or sand which allow tires to sink in and thereby slow the vehicle. To further slow the truck, ramps are built on an upgrade, except in some area where terrain necessitates that ramps go downhill. Ramps rang in length from 250 to 1,200 feet. Costs of installing ramps var from $8,000 for a 250-foot ramp in Pennsylvania to $245,000 fo a 1,200-foot ramp in Oregon. Terrain is a major factor in con struction costs. A survey by "Traffic Safety" magazine of 1 states and one Canadian province, indicates that 12 states hav escape ramps and find them to be worth the cost. Procedure followed by various states in the design and construction c ramps are described.

EFFECT OF LABILE CROSSLINKED SBR (STYRENE BUTADIENE RUBBER) ON PROPERTIES OF RADIAL TIRE COMPOUNDS

The cohesiveness of radial tire compounds incorporating SBR (styrene butadiene rubber) and BR (butadiene rubber) polymers is examined in relation to the effect of adding minor amounts of a labile crosslinked SBR polymer. Raw polymer blends were prepared and analyzed in terms of Mooney viscosity and cohesiveness. The effect of mixing conditions on cohesiveness and the rolling resistance of tires were evaluated. It was determined that for blends in all combinations of three common polymers (SBR-1778, SBR-1502, and BR-1203) the necessary cohesiveness for building radial tires can be obtained by adding minor amounts of SBR-LX, a labile cross-linked terpolymer containing 23.5% styrene, butadiene, and a small amount of a monomer with tertiary amine groups. The quality of SBR-LX required to reach a satisfactory level of cohesiveness depends on polymers used in the blend, equipment used to process the compound, and mixing procedures. Experiments using Dunlop's rotary power loss machine indicate that compounds containing a fraction of SBR-LX are likely to produce tires with lower rolling resistance.

BOUND ANTIOXIDANT STABILIZED NBR (NITRILE BUTADIENE RUBBER) IN AUTOMOTIVE APPLICATIONS

The performance of nitrile rubbers with polymerization-bound antioxidant in automobile engine compartments is examined in relation to heat aging performance. Nitrile rubbers, used in oil and fuel resistant applications since the 1930's, are produced by emulsion polymerization from butadiene and acrylonitrile. They have a balance of cost, processing ease, physical properties, oil and fuel resistance, and gas permeation resistance that makes them desirable for use in a number of applications. Bound antioxidant nitrile rubbers have undergone extensive laboratory and field performance evaluations in different automotive parts since 1975 to prove their value to the industry. They are used principally where conventional nitrile rubbers do not meet upgraded performance requirements, as replacements for epichlorohydrin copolymers (ECO) and polyacrylates (PA) for cost reduction, where performance deficiencies occur with extended field application history, and where properties of ECO and PA are not required but no other suitable material was previously available. Specific automotive applications include seals, fuel systems, and fuel hoses. Procedures and results of sour gasoline testing of various polymers is described. Only fluoroelastomer and bound oxidant nitrile rubbers lasted six weeks in this test. The service performance of bound antioxidant nitrile rubbers is consistently better than indicated from laboratory evaluations, and it is expected that the value of these polymers will appreciate considerably as price increases and petroleum shortages exert pressure on other specialty polymers made from more exotic monomer systems.

WIPE OUT (GM DELAYED PULSE WINDSHIELD WIPER MOTOR)

The delayed pulse wiper motor system devised by General Motors is described. The system solves the annoying problem of mist by providing a special delay mode, in addition to standard wiper operation at low, medium, and high speeds. The delay can be adjusted from a minimum very low speed operation to a maximum of approximately 12 seconds between wiper strokes, or any delay period between the two. System elements include a pulse relay, timing device, holding switch, drive cam, and override switch. The control circuit of the system is complicated and requires an orderly procedure for diagnosing problems. Repair procedures are outlined for various types of malfunction.

ARE YOU A RIPOFF MECHANIC? (UNNECESSARY CAR REPAIRS)

A team of researchers from the Johnson Environmental and Energy Center, working under contract to the Dept. of Transportation (DOT), investigated the effectiveness of 62 representative auto repair shops in detecting and repairing defects that had been deliberately induced in test cars. The team wanted to determine how much unnecessary and/or unsatisfactory repair work would be done. Additional information was collected regarding rates and possible billing for repairs not performed. The DOT study found that the consumer has only about a 50-50 chance of obtaining proper repair work at the correct price. There were shops that did unnecessary repairs, those that did not find the problem, and those that found the problem but used the opportunity to push other repairs. It is a known fact among auto repair shop operators that there are some incompetent and dishonest mechanics. More attention is being paid to the auto repair industry by car owners, consumer groups, and the government. One way to eliminate the dishonest or incompetent mechanic is certification. The reputable mechanic must take the initiative to earn customer confidence. He might post and/or distribute a list of principles (sample illustrated) to which he adheres in his practice. He must use the best diagnostic equipment and have the knowledge to interpret test results correctly. In addition, the auto mechanic must justify repairs to his customers.

NOBODY APPRECIATES THE TIRE. FACTS ABOUT TREADWEAR

Every tire has two effective diameters: rolling (tire under load), and free (unloaded tire at rest). The difference between the two is called the contact patch, or footprint, which represents tire deflection. Overloading a vehicle, using tires too small to support the weights involved, or underinflation increases deflection to a point where the center of the tread is raised off the road surface, causing rapid outer tread wear. Overinflation causes rapid center tread wear. Tread mileage is increased substantially by maintaining recommended tire inflation pressures. A rolling tire is subjected to centrifugal, acceleration, and deceleration forces. Tire rotational speed at the instant of contact with the road surface is zero, regardless of vehicle speed; the rotational speed at the opposite point is twice the vehicle speed; fore and aft positions are at vehicle speed. The tread material, therefore, should be of uniform stiffness. Traction waves in the casing behind the contact patch occur as a result of flexing at high-speed operation. Excessive camber causes rapid outside tread wear; too little camber causes rapid inside tread wear. High-speed cornering can cause tread shoulder wear. Incorrect toe adjustment results in a tread wear pattern called feathered edge or sawtooth. Cupped, dished, or scalloped tread wear is produced by a combination of mechanical problems such as loose ball joints, shock absorbers, tie rods, and idler arm bushings. Bias ply tires characteristically display a rapid wearing of the second rib in from each tire shoulder. Wheel imbalance and excessive lateral and/or radial runout will upset normal tire tread wear. The rate of tread wear is a good yardstick for measuring satisfactory tire life, but accelerated tread wear patterns are the keys to diagnosing problems causing tire wear.

THE ONLY WAY TO "DO IT RIGHT"..."WHEEL TO WHEEL" SECURITY CHECK...A COMPLETE 8-POINT INSPECTION OF THE STEERING AND SUSPENSION SYSTEM

Inspection procedures are outlined for the following steering and suspension components: ball joints, tie rod ends, bushings, idler arm, shocks, springs, brakes, and tires. Vehicle riding height (chassis height), a key to vehicle handling and control problems, is discussed. Steering and suspension problems caused by sagged springs are considered, including diagnosis by checking chassis height, and ways of correcting chassis height. Photographs and accompanying text are provided which illustrate typical tire wearing conditions resulting from specific suspension and steering problems. The results of combined suspension problems are discussed (loose suspension pivots plus an incorrect camber setting, worn upper control arm bushings plus toe-out condition, loose steering linkage plus an unbalanced condition). The effects on tread wear of loose wheel bearings, worn control arm bushings and idler arm, and wheel imbalance are included. Toe wear caused by incorrect toe-in or toe-out settings and camber wear caused by incorrect camber setting are depicted.

WEIGHT REDUCTION FOR FUEL ECONOMY

A special supplement presents separate discussions concerning alternative materials and manufacturing methods for reduced motor vehicle weight (and accompanying fuel conservation), based on a symposium (SITEV) held in Geneva during May 1979. A brief overview is presented of weight reduction in vehicles. The factors influencing the increased use of magnesium base alloys are discussed, with particular reference to their cost in comparison to aluminum. The properties and performance of the various forms of carbon fiber reinforced plastics are reviewed, including pre-impregnated tapes, thermoplastic molding material, pultruded composites, non-woven fabrics, and sheet molding compound. Rynite, a new thermoplastic polyethylene terephthalate polyester for automotive applications, is described. New test procedures are outlined, aimed at improving the correlation between laboratory tests and service performance of plastics. The significant weight savings offered by use of new, thinner glazing materials are discussed, and the design and development of a range of lightweight propeller shafts are examined. Design considerations and features of a self-contained, prefilled hydraulic clutch actuator are presented as an example of a weight-saving technique. An outline is provided of the implications and essential features of the Salplex light-weight electric harness, an example of multiplex data handling systems for automotive applications. A discussion of the preceding topics by the symposium participants follows, as well as an overall review of new developments by manufacturers and suppliers of lightweight materials for automotive applications.

VIRGINIA ESCORT DRIVER'S MANUAL

This manual provides information, including rules and regulations, legal requirements, safety suggestions, and reminders, to aid drivers who provide escort services for overdimensional loads (width in excess of 12 ft. but not greater than 14 ft.) on Virginia highways. An understanding of the provisions of this manual, and other safe driving rules applicable to every motor vehicle operator, is an essential requirement for certification as an escort driver and is a prerequisite for employment as such. Information is presented in the following sections: purpose of escort driver certification, general requirements for certification, certification program, safe driving practices, general regulations governing movement of overdimensional loads, duties and responsibilities of escort drivers, equipment for escort vehicles, proper escort procedures, don'ts of escort driving, emergencies, and study questions. A list of testing offices is provided.

FEDERAL MOTOR VEHICLE FLEET REPORT FOR FISCAL YEAR 1978 (OCTOBER 1, 1977-SEPTEMBER 30, 1978)

Data are compiled from information forwarded to the General Services Administration on Standard Form 82 by all Federal agencies operating vehicles in the U.S. and overseas. The tables summarize statistical data (inventory, costs, years of operation, mileage, fuel consumption) on agency-held, interagency motor pool, and commercial (leased) vehicles. These data are further categorized by all agencies and large fleets, worldwide and domestic. Selected data on five-year trends are included. No data are available for privately owned vehicles, although their use on official business is a significant fleet operations cost factor. Vehicle types included are sedans, station wagons, ambulances, buses, trucks, and truck tractors. Energy conservation tips and a glossary are provided.

3-D. "DON' DRINK AN' DRINE"...UH, "DON' DRIKE AND' DIVE"...I MEAN... (DRIVING COURSE FOR DRUNK DRIVING OFFENDERS)

Certain courts in Orange County, California are sending some of their DUI (driving under the influence of alcohol) drivers to the Academy of Defensive Driving (AODD) for three days of intensive training, lectures, and driving instruction. A 1977 study found that in the first year after a conviction, court-processed drivers (convicted and fined) were 78% more likely than the academy graduates to have another alcohol-related violation, 34% more likely to have an accident, 23% more likely to have a moving violation, and 40% more likely to have a license suspension. The AODD was begun in 1973 as an advanced driver training course for policemen, but it now includes individual courses for law enforcement personnel, adult DUI offenders, and juvenile DUI or open-container offenders. The AODD runs two 3-d ("Don't Drink and Drive") classes a week for three days each. There are intensive sessions of lectures, films, group discussions, hands-on driving practice through obstacles and hazards, and actual drinking-and-driving experiences that are built into the course. In each class, two people volunteer to drink until their blood alcohol level reaches .1, the legal level of intoxication. They then attempt maneuvers on the driving course which they had previously been practicing while sober. The volunteers are videotaped in the realistic drinking situation (barroom atmosphere) as well as in the driving environment. The videotapes are viewed and discussed by the entire class at the conclusion of the course.

TRAILER WEIGHT AND HITCHING UP

Information is provided by the Ford Motor Co. on the proper loading of recreational trailers. The load should be evenly distributed and should never exceed the manufacturer's rated towing capability of the towing vehicle. When loading the trailer, two considerations are gross trailer weight (weight of the empty trailer plus all trailer options and trailer's payload), and tongue weight (weight directly on the hitch ball, i.e. weight a trailer adds to the rear of car or pickup). It is essential that neither of these weights exceeds the towing vehicle capability. Other reminders include keeping the trailer's center of gravity low, storing heavy articles as near the floor as possible and lightweight items at a higher level, distributing the weight evenly, balancing the load from side to side, carrying only essential items, and securing all doors and drawers. For pulling lightweight Class 1 trailers with applicable vehicles, a weight-carrying ball hitch should be used. A load-equalizing hitch should be used for trailers weighing over 2000 lb. No more than 10% to 15% of the gross trailer weight should be on the hitch ball. An anti-sway device, built into the hitch or installed separately, is recommended for trailers over 3500 lb. Safety chains and a breakaway switch to activate the trailer's brakes are important if the coupling unit or hitch ball should fail. Trailer braking systems that have a direct hydraulic brake fluid connection with the towing vehicle's braking system are not recommended, since these increase the towing vehicle's stopping distance.

MOTOR CYCLES, CYCLISTS, CYCLING: SOME RANDOM THOUGHTS ABOUT THE WHOLE CYCLING SCENE

No-fault insurance is not seen as a viable policy for motorcyclists unless the financial risk is spread among those who inflict the damage, i.e. the automobile drivers. It is a fact that 75% of car vs. cycle accidents are the fault of the automobile driver. The cyclist has his rates raised substantially because he has more serious and expensive personal injury and vehicle damage than that sustained by the motorist even though he was not at fault. Despite the difficulty and expense in obtaining motorcycle insurance, buying insurance is the smart thing to do. The attitude of most motorcyclists is probably that they wear helmets because they want to, not because a law says so. Those who say they will not wear a helmet because they feel helmets are dangerous have made this decision based on emotion, not fact. A possible explanation for the cause of accidents in which a car strikes a motorcycle at an intersection is that the motorcycle is ignored because it does not produce enough of a threat to a car driver. A motorcyclist can reduce the accident potential of events over which he has control by adopting the attitude that he is invisible to fellow motorists.

THE GREAT DEBATE. SYNTHETIC OILS AND LUBRICANTS, AFTERMARKET OIL ADDITIVES, AND THE "IF" FACTOR

Background information on the development and characteristics of synthetic oils and lubricants is followed by a discussion of the pros and cons of their value to the car owner or driver. The four basic chemical classes from which the synthetics derive are the dibasic acid esters or diesters, the polyol esters, polyalphaolefins, and the alkylated benzenes. Overall, synthetics have the following advantages over conventional oils: increased gas mileage and prolonged engine life by decreasing engine temperature, by minimizing sludge, varnish, and acid formation, by minimizing metal-to-metal contact, and by providing quicker warm-ups; synthetics also permit longer periods between oil changes. Some questions are answered concerning the "IF" factor (synthetics' possible advantages for a particular car owner). Synthetic oils cannot be used as "break-in" oils. If a car's engine was broken in with the factory installed oil, the use of a synthetic will not void a new-car warranty. The Armed Forces use synthetics in Arctic areas because of their low-temperature qualities, but not routinely because of expense. Motorists are not generally using synthetics probably because of bad experiences with some of the earlier synthetics. In terms of economics, the 25,000 mi. cost of synthetic oil is $38.75, compared to about $38.00 for a conventional petroleum-based oil. The synthetics offer economic advantages in terms of fuel consumption and maintenance, but only if the engine is in good condition. The results of an Army study on aftermarket oil additives revealed that many of these additives offered very marginal improvement in dispersancy and detergency at a cost of potential performance problems as a result of high foaming tendencies and increases in low-temperature fluidity properties.

USER'S MANUAL: FHWA (FEDERAL HIGHWAY ADMINISTRATION) LEVEL 2 HIGHWAY TRAFFIC NOISE PREDICTION MODEL, STAMINA 1.0. FINAL REPORT

Modifications to the TSC MOD-04 highway traffic noise prediction program to extend the scope of problem formulation are described. The FHWA (Federal Hwy. Administration) Level 2 Highway Traffic Noise Prediction Model features: revised vehicle reference noise emission levels, specification of site-specific (excess) attenuation, English/metric and metric/English conversion of engineering units for both input and output data, common input data format with TSC MOD-04 model, and user options to improve operating efficiency. Problem formulation, input data requirements, output error messages, examples of usage, and computer program documentation are presented. FHWA has given the Level 2 program the acronym STAMINA 1.0 for Standard Method in Noise Analysis (Version) 1.0. Appended are the basic formulation of the computerized prediction model, declared size of arrays, allocation of common block data, architecture of prediction code, and subprogram descriptions.

SAFETY AT NARROW BRIDGE SITES

A study was undertaken to define the narrow bridge problem, to appraise the effectiveness of corrective measures, and to develop guidelines for corrective treatment at various bridge sites. A nationwide survey indicated that there may be 60,000 highway bridges in the U.S. that are deficient in width. Field studies were conducted at 25 selected bridge sites in seven states. Driver performance in terms of speed and lateral position was determined for each site, and modifications of signing and delineation were made at several sites. Before-and-after accident experience was available for one section of road where corrective treatments had been applied to several narrow bridges. A bridge safety index (BSI) was developed as the combination of ten individual bridge site rating factors: clear bridge width, bridge lane width/approach lane width, guardrail and bridge rail structure, approach sight distance/85% approach speed, 100 plus tangent distance to curve/curvature, grade continuity, shoulder reduction, volume-capacity, traffic mix, and distractions and roadside activities. For most bridges, the BSI can reasonably estimate the relative degree of hazard of a site in comparison with other sites. The BSI should be used on a trial basis to develop information for verification and modification of the technique. When employed by highway agencies, the collection and analysis of additional information should result in a revised concept of greater precision and effectiveness. Appended are driver behavior studies (with photographs), results of narrow bridge survey, and an annotated bibliography.

ADAMS CALLS FOR MAJOR LEAP IN AUTOMOTIVE FUEL ECONOMY

Production of a national fleet of passenger cars with fuel efficiency averaging between 40 and 50 mpg by the year 2000 is a technically feasible and realistic goal, Secretary of Transportation Brock Adams stated before the Senate Com. on Commerce, Science, and Transportation. Adams released a preliminary report on a Mar 1979 conference he convened in Boston on the car of the future. The report, prepared by Raymond L. Bisplinghoff, of the National Res. Council, identified promising areas which offer great potential but where basic research is lacking: the diesel engine (information needed on emission control), reinforced plastics (data needed on design, mass production, and disposal characteristics), and engines fueled by nonpetroleum sources (information needed on emission characteristics). Secretary Adams called for a basic research program to be jointly conducted by the auto industry, private research laboratories, universities, and others, rather than by the Federal government. The logistics and funding of such a national program is to be discussed at a May 1979 major meeting of automotive experts. The need for the program is based on three factors: continued domination of the car as a transportation mode, adverse effect of continued dependence on foreign oil, and lack of initiative by manufacturers. Adams also said that serious consideration must also be given to the development of alternative fuels.

SCHOOL BUS DRIVER HIRING TECHNIQUES

Criteria for screening, testing, and hiring school bus drivers have been developed by William R. Kyser, supervisor of training and loss control of the Houston Independent School District transportation department. Kyser's employment model is structured around a set of "predictors," which provide an insight into the future driving behavior of the applicant. Predictors are grouped in tiers, of which the first (most important) tier includes driving record, criminal record, age, and amount and type of driving experience, and should determine whether the hiring process should continue. The second tier includes a behind-the-wheel test, medical exam and history, and questions on use of intoxicants and cigarettes, marital status, and motorcycle ownership. The final predictor is the applicant's performance and attitude during classroom and behind-the-wheel training. The predictors, if properly linked, may prove a system for behind-the-wheel behavior prediction, and should provide an organization with positive information concerning the probability of the applicant's future success as a safe driver. The system offers through the stages of pre-selection, selection, and training, an enhancement of the decision-making process involved in hiring a professional driver.

MINNESOTA'S 56-HOUR DRIVER TRAINING PROGRAM (SCHOOL BUS DRIVERS)

The Center for Driver Education and Safety at St. Cloud State Univ., in cooperation with the Minnesota Dept. of Education, has developed a series of school bus driver training workshops which exceed the minimum recommended by Highway Safety Standard 17. These workshops, which total 56 hours of instructions, are provided to school districts and contract operators free of charge (through a grant of 406 funds from the Minnesota Dept. of Public Safety). Drivers are encouraged to participate initially in a basic workshop, a three-hour session designed to familiarize drivers with the task of school bus driving. Advanced workshops are conducted for those who want more in-depth analysis of the topics included in the basic workshop (driving skills, vehicle maintenance, human relations, accident and emergency procedures, and laws, rules, and regulations). Each topic is discussed within a three-hour time frame (total of 15 hours). In order to address the needs of drivers who transport special students, a three-hour workshop has been developed based on the National Hwy. Traffic Safety Administration's School Bus Driver Instructional Program. Another three-hour workshop addressed liability and insurance when transporting students. The American Red Cross' Multi-Media First Aid Course is offered to school bus drivers including nine hours of theoretical and practical experience. The National Safety Council's Defensive Driving Course with School Bus Supplement, a nine-hour program, and a six-hour instruction program in emergency driving techniques are offered. The Center for Driver Education and Safety hosts the annual State School Bus Driver Roadeo, and conducts local and regional roadeos by request.

STATEWIDE INSTRUCTOR TRAINING GOAL OF FLORIDA DEPT. OF EDUCATION

In 1974, the Florida Dept. of Education began its program to train school bus driver instructors, the goal being to have a qualified instructor in every district in the state. All school superintendents and transportation directors were invited to participate in the program and criteria were explained for persons who would attend instructor workshops. Three-day workshops were conducted to provide potential instructors with a detailed explanation of the National Hwy. Traffic Safety Administration School Bus Driver Curriculum Package. The emphasis was placed on the development of teaching skills rather than on school bus driving skills, since most of the participants were already certified school bus drivers. The curriculum package given to each trainee consisted of five documents: a course guide designed to aid the training administrator and instructors in preparing for the course, instructors' guides for both basic and advanced units, and two trainee study guides designed to serve as student texts/workbooks. In 1976, an advanced course, including behind-the-wheel training, was offered to round out the instructor training. The positive results of Florida's training program have been seen not only in driver attitudes but also in accident statistics. For example, during the 1974-1975 school year, school buses averaged 96,158 mi. per accident, compared to 142,540 mi. per accident in the 1977-1978 school year.

DRIVER TRAINING IN DEKALB COUNTY, GEORGIA (SCHOOL BUS DRIVERS)

The DeKalb School System (Atlanta area), has seven driver education ranges, first used for school bus driver training in Aug 1978. The school systems driver training course consists of four phases: classroom, simulation, on-street, and range. The primary purpose of the classroom phase, which uses audiovisual aids, is to provide learning activities enabling the drivers to demonstrate the visual-perceptual skills necessary for driving through the use of the SIPDE (search, identify, predict, decide, execute) process, and to demonstrate the commentary driving technique. The participants demonstrate a practical application of the SIPDE process in the simulation phase. Half of the drivers then participate in the on-street exercise, while the remainder are involved in range driving. In the on-street portion, each instructor takes two drivers through an 11-minute lesson to perfect driving technique, followed by 11 minutes of performance testing (observing; communicating; adjusting speed; positioning; judging time, space, and distance; and hazard perception). During the range phase, two drivers are assigned to a 16-, 27-, and 66-passenger bus in which they alternately perform basic and advanced maneuvers (instruction and practical application for three 55-minute and two 55-minute periods, respectively).

OGDEN, UTAH'S ONE-OF-A-KIND BUS. MOBILE CLASSROOM CONTAINS SAFETY TRAINING FACILITIES

The Weber County School District in Ogden, Utah, has developed a safety training program which addresses school children, PTA and other civic groups, and includes school bus driver training. It centers around a unique, self-contained, fully-automated, mobile training bus. The bus has central heating and air conditioning, carpeting, indirect lighting, piped-in music, and wood paneling. It contains a complete movie theater, with 8, 16, and 35 mm slide projection and full sound reproduction capabilities. The bus is equipped with power generator as backup to external systems. The mobile training center, which will hold approximately 30 pupils, is designed for 40-minute sessions of personalized instruction concerning the problems of traffic, pedestrian, bicycle, and school bus safety and includes presentations designed to educate new bus drivers. The atmosphere created by the Safety Training Bus generates attentiveness and interest.

NEW BUSES AND NEW TRAINING FOR COLORADO (SCHOOL BUS) DRIVERS

Arapahoe School District 6 in Littleton, Colorado, has an extensive school bus driver training program in which all drivers are required to attend 40 hours of formal training. Acquisition of an International S-line bus with International DT-446 engine will require that drivers have a new training session on the use of the new equipment. Plans are being made for International Harvester instructors to advise drivers on the use of the new buses. Of two driver training programs in the district, the primary one is concerned with driving in metropolitan traffic areas, the other involves field-trip driving. Two handbooks are issued to all drivers: a standard school bus driver handbook, and an advanced driver training pamphlet which is updated periodically. Much of the advanced book deals with recognizing an automotive problem while out on the road, determining what is wrong, and deciding whether there is an immediate solution. Defensive driving is emphasized in the Arapahoe driver's manual. Special courses are given by the school district to preschoolers and their families concerning entering, leaving, and riding in school buses.

EVALUATION OF THE WISCONSIN DRIVER IMPROVEMENT PROGRAM. EXECUTIVE SUMMARY

Driver records and other data of subpopulations of drivers who completed three components of the Wisconsin Driver Improvement Program were examined to determine program impact on crashes, traffic violations, and drinking/driving incidents, and to make comparisons between program models and approaches in order to determine the most effective measures within the subprogram structure. The three components were Driver Interview (DI), Group Dynamics Traffic Safety School (GD-TSS), and the Demerit Point Reduction School (PRS). It was found that the differences between treatment and control groups of the DI were slim in most cases and not always favorable to the treatment group. The GD-TSS and the PRS showed better records than the DI activity. In order to reach conclusive results on the effect of GD-TSS and PRS on driving behavior, a controlled study is needed. No support was found for the theory that the time elapsed between violations increases with the number of accumulated points. It was suggested that the drinking problem (as expressed in the number of driving while intoxicated convictions) tends to run a "maturation" course. In some cases the record in post-school attendance at GD-TSS alcohol education-treatment/rehabilitation was poorer than in the preschool attendance.

TOWARDS A SOCIAL PSYCHOLOGY OF THE TRAFFIC ENVIRONMENT

The literature is reviewed concerning human factors and traffic accident causation, the relationship of specific characteristics (experience, demography, personality) of driver groups to driver behavior, driving behavior and cultural values and individual attitudes, accidents as social events, and social psychology and driving behavior. An approach is described which may permit better understanding of the psychological basis of behavior in the traffic environment. The basic theoretical position implicit in the method is that people's actual behavior is consistent with underlying attitude systems, regardless of expressed values and opinions. The method involves a fundamental analysis of public opinions aimed at eliciting information about basic feelings and attitudes. The first of a set of steps is to conduct interviews with experts to get some idea of the "official" opinions. Members of the public are then interviewed in a group setting, using a variety of techniques derived from such sources as psychoanalytic theory, T-Group procedures, and objective psychology. On the basis of these interviews, schedules are constructed and administered in a series of semi-structured interviews with a small, random sample of the public. A questionnaire is then constructed from the assembled data, and administered to a large, random sample of the population. Results are outlined from a study which applied this methodology; the three broad areas of interest were sources of hazard on the road, reactions to a near accident or collision, and the image o the dangerous or bad driver. It was found that drivers se certain properties and actions of other drivers as major element in the traffic environment, and as major sources of hazard. Driving was shown to be a social situation in which interpersonal reactions are of great importance, the reactions appearing to follow established principles in social psychology.

SENSIBLE SENSOR

The development of a sensor that knows when an automobile crash is serious enough to deploy air bags is discussed. Automotive air bags have evolved from research in the field of aviation safety. The crash sensor, developed by the Essex Group of United Technologies, will be used by Ford in its 1981 model year production. As the heart of air bag systems, the sensor determines whether an impact is severe enough to deploy the air bag. Most sensor types feature a spring mass design. Each sensor has a weight held in place by a tensioned leaf spring or magnet. In a crash of sufficient G forces, weight overcomes the force of the spring or magnet and closes an electrical contact. The air bag is then deployed with a gas propellant. In some cases, sensors operate within a time interval of less than 10/1,000th of a second. Air bags inflate and begin deflating within 1/25th of a second. The Essex gas-dampened sensor has the advantage of being a true velocity integrator, i.e., the sensor measures velocity change as well as G forces experienced in a crash and combines these measurements to determine whether air bags should be deployed. Statistics indicate that approximately 12,000 automobiles, factory-equipped with airbags, traveled an estimated 902 million passenger miles from 1972 to 1978. The accident fatality rate for cars not equipped with air bags was estimated to be over 2 1/2 times higher than for air bag equipped cars.

AIR BAGS: A SPECIAL ISSUE

Information about air bags and the status of the Dept. of Transportation's (DOT) automatic restraint standards is provided in a special issue by the Insurance Inst. for Hwy. Safety. Automatic crash protection requirements of DOT specify minimum levels of automatic protection for front-seat occupants in frontal and front-angle crashes at speeds up to 30 mph. Cancellation or delay of these requirements may force air bag manufacturers to terminate their efforts. Manufacturers have invested nearly $20 million to design, develop, and test air bag system components. DOT estimates that about 9,000 crash deaths and 65,000 serious injuries would have been prevented if all cars on the road in 1975 were equipped with automatic restraints. In mass production, air bags will increase car prices by $200-$250. Although some Congressmen (e.g. Rep. John Dingell) do not favor the use of air bags, increased levels of crash protection have been affirmed by the courts and Congress and public opinion polls consistently show a strong preference for the safety and convenience of automatic crash protection. Personal experiences of people who survived automobile crashes because of air bags are presented, as well as information on the myths and realities of air bags.

WHEELCHAIR TIE-DOWN/PASSENGER SEAT PROTOTYPE DEVELOPMENT (FOR RAIL PASSENGERS)

The development of a wheelchair tie-down system for use in rail passenger cars is outlined. As part of the Canadian government's 1976 improvement program for rail passenger cars, a contract was awarded to design and fabricate prototype wheelchair tie-down passenger seats for persons with physical disabilities. Objectives of the contract were to immobilize wheelchairs of different dimensions and structures with passengers aboard during travel on a high-speed train, to provide appropriate seating for passengers who want to switch from wheelchairs to seats during a long trip (3-6 hours), and to provide for elderly and semiambulatory persons who are not wheelchair-bound. Available seating space for each handicapped passenger is 41 inches wide and 57 inches long along the train axis, one side facing the bulkhead and the other side facing seats. The wheelchair tie-down concept consists of an independent unit connected to a strong bulkhead, or used free-standing, with the addition of braces. A steel structure covered by a fiberglass shell is bolted to the floor tracks and the bulkhead. If free-standing, the unit is through-bolted to floor tracks supported by braces. Two arms swing out at 45-degree angles and are anchored to the structure where it meets the floor. To accommodate different wheelchair widths and wheel diameters, arms pivot around their anchor points and have telescopic adjustments. Two-point hooks on the end of arms are placed over the wheels. A lever locks the wheelchair by pressing wheels against the shell and the floor. A support for the head and back is provided, and a belt at waist level gives extra support for wheelchair-bound persons with upper body control problems. Two prototype units have been built and have undergone G-loading tests. Drawings and specifications of prototypes, and photographs are included, and a test report prepared by TES Limited, Ottawa (TES-C225-1) is appended.

SAFETY IN CONSTRUCTION AND MAINTENANCE WORK ZONES AND TRANSPORTATION OF HAZARDOUS MATERIALS

Ten papers are compiled on the following aspects of transportation safety: work zone safety; liability for improper traffic signaling, signing, and pavement markings; status of traffic safety in highway construction zones; crash test evaluation of temporary traffic barriers; evaluation of timber barricades and precast concrete traffic barriers for use in highway construction areas; accident analyses of highway construction zones; computer model for liquefied natural gas and liquefied propane gas risk simulation; crash testing of nuclear fuel shipping containers; safe transport of munitions; and special problems encountered by highway agencies and contractors in designing work zone layouts as related to tort liability.

WORK ZONE SAFETY (ROADWAY CONSTRUCTION AND MAINTENANCE SITES)

The Federal Hwy. Administration's (FHWA) 1976 program to improve safety in construction and maintenance zones pressed for improvements in the Manual on Uniform Traffic Control Devices (MUTCD) relating to traffic control at work sites, initiated a number of training programs on work site safety, allocated $2.5 million for research in innovative safety practices in work areas, and measured progress through an extensive national review of safety practices at work sites. Although safety at work sites has improved, there are still major problem areas. Accident data are still not used to identify safety problems at work sites. The use of barrier and guardrail to protect the work area has improved, but there are still too many blunt-end and transition hazards. Construction materials and equipment are often stored hazardously close to the roadway. In many cases, major dropoffs are not effectively shielded from motorists. Many of the present work zone safety problems relate to the lack of knowledge on how to improve traffic operations at work sites, which is reflected in the vagueness of MUTCD criteria. If considerably more progress is not made in improving work site safety, the FHWA will be forced to consider more stringent requirements for work site activities, including traffic control plans developed as a prerequisite for project approval. In addition, FHWA must provide additional guidance on driver needs in work sites, based on human factors research.

LIABILITY FOR IMPROPER TRAFFIC SIGNALING, SIGNING, AND PAVEMENT MARKINGS. ABRIDGMENT

Although there has been a significant increase in tort litigation against highway departments, court decisions and recent tort claims acts recognize that states and state agencies should not be held liable for negligent performance of governmental functions that are discretionary in nature (i.e. involving the power to make choices among valid alternatives and to exercise independent judgment). The general view is that the state is not liable for negligence in the performance of functions which involve a high degree of discretion but is liable concerning ministerial or operational level tasks. Ministerial tasks are said not to require any evaluation or weighing of alternatives before performance of the assigned duty. Immunity usually attaches to governmental decisions about signs, signals, or markings if the government shows that the plan, design, or program has been adopted after reasonable consideration and deliberation. Some decisions are clearly more discretionary than others, and court decisions differ on that account. The trend appears to be that only decisions made at a policy level or those involving a consideration of policy factors are discretionary. The result has been to narrow the duties that are discretionary; more decisions that once would have been immune from liability no longer enjoy that protection. The majority of the courts hold that only decisions made at the planning level, rather than at the operational level, fall within the discretionary function exemption. It would appear that the decision on whether to provide signs, signals, or markings is the exercise of immune discretion at the planning level, but that negligence thereafter in provision or in maintenance of signs is less likely to be protected from liability.

HS-026 930

STATUS OF TRAFFIC SAFETY IN HIGHWAY CONSTRUCTION ZONES

Evidence is increasing that existing traffic control practices do not always provide adequate safety in construction zones. Numerous accident studies have shown that the total accident experience in construction zones increased from 2% to 119% during construction periods, and that the accident increases were highly related to construction activity. A study in one state showed that accidents decreased dramatically when construction-zone traffic control practices were improved. All phases of traffic control in construction zones can be improved, including planning, designing, and management. More effective planning and design of construction-zone traffic control should require a step-by-step planning process including collection of roadway, traffic, and construction data; selection of basic zone type and scheduling; formulation of a speed control strategy; determination of geometric design elements; and selection of traffic control devices and methods. More effective management of construction-zone traffic control should include improved public information, training of field personnel, review and modification of traffic control, removal of inappropriate devices, and improved maintenance of traffic control devices.

CRASH TEST EVALUATION OF TEMPORARY TRAFFIC BARRIERS

Three currently used temporary barrier devices were evaluated in crash testing in order to determine their performance limits: 250-mm. x 250-mm. (10-in. x 10-in.) timber barrier, W-beam barrel barrier, and type X curb. These traffic barriers were subjected to controlled impacts with full-sized 2040-kg (4500-lb) automobiles impacting at angles from 7 degrees to 16 degrees at speeds from 56 kph (35 mph) to 90 kph (56 mph). The timber barrier had minimal redirection capability. The upper rail members were not functional and exhibited a potential for spearing both vehicles and occupants. The lower base was readily mounted by vehicles at nominal speeds and angles. Use of this barrier for containment and redirection is not recommended. The base with upper railings removed could be used for very low speed operations, where speeds and impact angles are low and traffic consists of automobiles only. The W-beam-barrel design was an effective containment barrier for the vehicle impacting at 73 kph (45 mph) and an angle of 15 degrees. The type X curb was ineffective in redirecting vehicles; it was readily mounted, and even at angles of 8 degrees it did not appear to be capable of redirecting the vehicle at 56 kph (35 mph). The fact that the test vehicle did not completely go over the test barrier is attributed to the deceleration force imparted by the snagging of the splice plate (a non-repeatable means of deceleration), which caused severe damage to both vehicle and barrier. (The timber barrier has been banned by the Federal Hwy. Administration from further applications).

EVALUATION OF TIMBER BARRICADES AND PRECAST CONCRETE TRAFFIC BARRIERS FOR USE IN HIGHWAY CONSTRUCTION AREAS

Results are summarized of a study of the performance of the timber barricade, and a comparison of its characteristics and performance with those of the precast concrete traffic barrier. The study included a traffic accident analysis of the construction zone on I-495 in northern Virginia where the timber barricade was employed; a comparison of the technical, operational, and economic feasibility of the timber barricade and the precast concrete traffic barrier; and a review of the legal requirements for temporary barrier systems. The frequency of accident occurrence during construction on I-495 was approximately 119% higher than that before construction. Of the reported crashes during construction, 52.5% involved vehicle contact with the timber barricades. Of the vehicles involved in crashes with the barricades, 73.5% straddled or penetrated the barricades. Thus, for this site, the timber barricades were ineffective as positive barriers. From the technical, operational, and economic analyses, the precast concrete traffic barrier appeared to be superior. Since the completion of this study, the Federal Hwy. Administration has banned the use of the timber barricade as a positive barrier on any Federal or Federal-aid project.

ACCIDENT ANALYSES OF HIGHWAY CONSTRUCTION ZONES

Accident analyses were conducted for 79 construction projects in seven states. Time-trend analysis showed that construction zones caused an average increase of 1.60 accidents/mo. The total number of accidents increased by 7.5%, the accident rate by 6.8%. Of the projects studied, 31% had accident decreases during construction; 24% had rate increases of more than 50%. Three case studies of zones with rate increases of 40% or more indicated that construction-related accidents were responsible for the increases. Total accident number and rate analyses showed a slight shift toward property-damage-only accidents. Linear regression analyses indicated a strong correlation between traffic control devices and construction fixed-object accidents, and a poor correlation between construction-zone variables and ran-of-road accidents. Accident number analysis showed a substantial increase in fixed-object, head-on, and rear-end accidents, but a decrease in ran-off-road and sideswipe accidents. Various analyses implicated reduced traffic speed in accident increases. Six- or eight-lane Interstate projects reduced to one lane in each direction had accident rate increases of over 100%, but those reduced to two lanes in each direction had increases of only 5%. Four-lane, divided Interstate projects reduced to two-lane, two-way had percentage increases more than double those in which the roadway was reduced to one lane in each direction. Five-lane, undivided highways with two-way left-turn lanes reduced to two lanes had the highest rate increase of all road types. Two-lane roads reduced to one-way alternating operations had worse rates than those placed on new alignment. Bridge work, followed by road reconstruction (on the same alignment), had the largest percentage of accident rate increases.

COMPUTER MODEL FOR LIQUEFIED NATURAL GAS AND LIQUEFIED PROPANE GAS RISK SIMULATION

Early in 1971, the National Transportation Safety Board recommended a general framework for risk analysis of hazardous materials. The HAZ-EX computer program was developed to provide analysis of the risk to the public associated with the transportation of hazardous materials. The program is intended to give project designers safety information on routes and sites during the planning stages of a project. The HAZ-EX program is a modular design whereby each module is an element of the risk analysis. The elements range from the simulation of spill dynamics to human injury criteria. The advantage of a modular approach is that updated data or alternative phenomenon descriptions can be inserted. The program capability includes material storage and ship, pipeline, truck, and rail transportation modes. Program-effects analysis capability includes prediction of injury due to toxicity, radioactivity, flammability, and explosivity. By selecting the appropriate combinations of modules, rapid comparisons can be made of site, transportation mode, transportation routes, and system alternatives. The HAZ-EX program has been applied to the storage and bulk transportation of liquefied natural gas and liquefied propane gas. The use of realistic injury and damage criteria as well as accurate physical phenomena description are extremely important. The advantage of a computerized model is speed. A few pages of computer output can apprise decision makers of the safety aspects of a proposed movement of hazardous materials. If a working definition of acceptable risks were then available, the reviewer could be easily satisfied as to the acceptability of an applicant's plans as proposed or whether modifications would be necessary. The efficacy of modifications can be evaluated by rerunning the model.

CRASH TESTING OF NUCLEAR FUEL SHIPPING CONTAINERS

A program begun in 1975 investigated the dynamics of extra severe transportation accidents and evaluated state-of-the-art computational techniques for predicting the dynamic response of shipping casks involved in vehicular system crashes. One phase of this research used computational methods to predict the effects of the accident environment and subsequently to calculate the damage incurred by a container as the result of such an accident. A second phase involved the testing of one-eighth-scale models of transportation systems. Through the use of instrumentation and high-speed motion photography, the accident environments and physical damage mechanisms were studied in detail. After correlating the results of the first two phases, a full-scale event, involving representative hardware, was planned. The selected accident scenarios included crashes of a tractor-trailer rig carrying a spent nuclear fuel cask into a massive concrete barrier at 100 kph and 130 kph; high speed (130 kph) impact of a locomotive into a truck-mounted, spent nuclear fuel cask at a simulated grade crossing; and impact at 130 kph of a special rail car carrying a spent nuclear fuel cask, followed by exposure to a fire. To date, the first two test scenarios have been completed. Results of the program so far indicate that both computational techniques and scale modeling are viable engineering approaches for the study of accident environments and physical damage to shipping casks.

SAFE TRANSPORT OF MUNITIONS

The Dept. of Defense (DOD) is conducting a study to determine procedures and methods that are technically and operationally feasible and economically acceptable to prevent, or limit, the effects of explosive incidents in rail cars, and mass detonation of containerized munitions in port areas and aboard ships. The study was initiated after incidents at Roseville, Calif. (28 Apr 1973) and Benson, Ariz. (24 May 1973) involving explosions on trains loaded with high-explosive bombs. Selected DOD components, whose inherent mission, expertise, and physical assets are appropriate to developing solutions, will conduct technical and operational feasibility studies. Each participant (i.e. the Army Ballistic Res. Lab., the Army Ammunition Center, the Navy Weapons Center, and the Military Traffic Management Command) will coordinate its area of study with other governmental and industrial organizations. The 13 tasks of the STROM (safe transport of munitions) study have been categorized into six major areas: background information, traffic patterns, equipment, fire protection, buffering, and sea containers. The STROM study, including a final report, is to be completed within 33 months, ending in Sep 1980. The total cost is estimated to be almost $3 million, which will be funded by both the Army and the Navy.

TORT LIABILITY: SPECIAL PROBLEMS ENCOUNTERED BY HIGHWAY AGENCIES AND CONTRACTORS IN DESIGNING WORK ZONE LAYOUTS

The principles of tort liability apply generally, whether the case is one of highway design, maintenance, or construction. Construction zones present special problems in that they are at variance with the motorist's normal expectations. Adequate warning devices and barrier safeguards are therefore required. Most tort liability cases discuss what is not adequate; what is adequate remains a vague item in terms of legal discussion. In light of this, the following topics are discussed: court guidelines which indicate general responsibilities in the case of accidents resulting from alleged highway defects, Federal highway safety programs and requirements, and recent cases that provide first-hand knowledge of judicial treatment of the subject matter.

COLD TEMPERATURE TESTS OF HEATED/ INSULATED BATTERY FOR AM (AMERICAN MOTORS) GENERAL DJ-5E JEEPS

Field tests were conducted to evaluate ways of maintaining electric vehicle batteries in an operable condition, i.e., electrolyte temperature above 50 degrees F over weekend "cold-soak" periods in ambient temperatures as low as 15 degrees F. The Postal Service operates about 400 electric vehicles, predominantly American Motors General DJ-5E Jeeps with a 1300-lb, 3.22-cubic foot, 54-volt Gould propulsion battery. Numerous vehicles were assigned to delivery routes in low ambient temperatures which affected battery performance. Field installation of foil-faced insulation on inservice batteries maintained a higher electrolyte temperature than unwrapped batteries exposed to 15-degree F ambient temperatures. While overnight "cold-soak" in 15-degree F ambient temperatures did not significantly reduce battery capacity because of the heat retained after completion of the charging cycle, weekend "cold-soak" at this temperature reduced battery capacity so that vehicles could not complete assigned routes. Test results indicated that a heat source of about 300 watts with a foil-faced insulation cover and heat cycling by thermostatic control would maintain batteries in an operable condition.

RISK ANALYSIS OF AN AUTOMATED ASSEMBLY LINE OPERATION

Risk analysis techniques were applied to the automotive industry to assess equipment and/or product damage caused by system failures. The client was interested in determining what System elements were responsible for damage and whether the system could be repaired at reasonable cost and with a high probability of success. In addition to fulfilling stated objectives, risk analysis identified a high probability of assembly line downtime due to electronic control failures. Analysis included microcomputers, electromechanical interface between computers and machines, operator-computer interface and the operator, and computer-encoder-conveyor interface. Findings demonstrated that damage failures were due to loss of synchronization between the assembly line and the control system, erroneous job data, and failed safety circuits. Reliability improvements were recommended in the areas of safety circuits, system elements requiring safety circuit intervention, and control system hardware. Among the recommendations were safety circuits improved to assure high probability (by monitoring or by redesign), redesigned conveyor position, redundant checks for operator job entry data, and preventive maintenance on machine and conveyor braking systems. It is noted that risk analysis is most cost/effective when performed in the design phase.

GM'S NEW X-CARS

Testing of General Motors' 1980 compact cars ("X-cars"), designed to offer good fuel mileage, is reported. Front-wheel drive in compacts eliminates a large driveshaft hump, leaving more interior room, and an engine mounted from side to side rather than fore and aft shortens the hood. Aerodynamic body styling and a radial ply tire with lower rolling resistance than that of conventional radials improve fuel economy. Four 1980 models (Buick Skylark, Chevrolet Citation, Oldsmobile Omega, and Pontiac Phoenix) share most major components, such as engine, transmission, wheels, tires, brakes, steering, and basic body. They differ primarily in front and rear body styling and in the instrument panel design. Test results on these cars pertain to engine and drive train, front and rear accommodations, interior noise level, ride, normal handling, accident avoidance ability, brakes, safety features, bumper protection, controls and displays, climate control, and periodic servicing. General Motors is evaluated as very successful in the design of 1980 compact cars. Price data are tabulated.

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL CRASH VICTIM SIMULATION, VERSION 4. VOL. 1. FINAL REPORT

Equations of planar motion are presented for vehicle occupants in a crash environment, in a study focused on automotive safety, crash and occupant dynamics, restraint systems, and whole-body responses. Features of the analytical model include: eight-mass 14-degree-of-freedom representation of the human body; extensible multijoint neck and flexible shoulder joint; simulation of biodynamic muscle contraction as a time-dependent phenomenon; modeling of contact between victim and vehicle by means of contact-sensing ellipses attached to the body and a real-line representation of the vehicle interior and exterior; specification of material properties for vehicle and occupant in terms of general force-deformation relationships; structural collapse resulting from collision or occupant contact forces; an air bag model that predicts forces on the occupant by solving gas thermodynamic equations; 4-degree-of-freedom energy-absorbing steering assembly; simple energy-absorbing belt restraint submodel with three independent straps and advanced belt restraint submodel with up to seven straps, two slip points, and vehicle-sensitive or webbing-sensitive inertia reels; and tabular 3-degree-of-freedom vehicle accelerations.

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL CRASH VICTIM SIMULATION, VERSION 4. VOL. 3. FINAL REPORT

To assist professional computer programmers responsible for program maintenance and improvement in the Motor Vehicle Manufacturers Association two-dimensional crash victim simulator, the organization of the computer program according to five processors and their interactions is detailed. Program organization and flow, packing techniques, binary output formats, and auxiliary program outputs are discussed for each processor. Design information about special output subprocessors is presented, and conversion of the computer program for use on various computer systems is examined.

VALIDATION COMMAND LANGUAGE (1979 VERSION). FINAL REPORT

Features and use are described of the Validation Command Language (VCL) computer program developed to aid automotive safety researchers in quantifying comparisons between impact test results and predictions of mathematical simulations. The VCL has been structured to provide user ease, self-contained analytical power, and graphical output capability. It is divided into five major divisions (identification, assessment, preparation, comparison, and presentation). Anticipated applications of the VCL software are: manipulation, analysis, comparison, and graphic presentation of dynamic impact data; simplification of procedures necessary for the quantitative validation of mathematical models; and establishment of possible correlations between experiments and theoretical estimates. Additional formula interpreter software carries manipulation and analysis capabilities further. If an analytically-based performance criterion is devised, the user can invest the formula as data and retrieve results with no additional postprocessing. Detailed program information and tables are provided.

SURVEY OF ANTILOCK SYSTEM PROPERTIES: MOTOR TRUCK BRAKING AND HANDLING PERFORMANCE STUDY. FINAL TECHNICAL REPORT

Results of laboratory tests performed on five commercial air brake antilock systems are discussed (Bendix, Eaton, B. F. Goodrich, Kelsey-Hayes, Wagner). Operational features of all systems covered a variety of characteristics: single/double solenoid air valves; pneumatic logic; and high frequency pulse-rate solenoid modulation. Antiskid hardware (air valve and logic module) was located in a laboratory area and connected by trunk lines to a hybrid computer. Single wheel dynamics were simulated on the analog computer and generated the required wheel speed signal to the antiskid logic module. Brake pressure was transduced from brake cans connected to the antiskid air valve and returned to the analog computer for the calculation of brake torque. The matrix of simulated test conditions, represented by parameters on the analog computer, included three repeats for each variation in wheel load, wheel inertia, tire-road friction, and initial velocity. Different hardware and control strategies used by the five antilock systems produced significant differences in wheel speed cycling behavior. A general feature shared by most systems was the recurrent philosophy of slow brake pressure application and quick release. This antiskid data base can be used to approximate and represent antiskid system performance in large-scale vehicle simulations. Additional information and tables on the analysis of antiskid systems are appended.

USE OF PERSONAL MONITOR TO MEASURE COMMUTER EXPOSURE TO CARBON MONOXIDE IN VEHICLE PASSENGER COMPARTMENTS

A study was made of exposure to carbon monoxide (CO) by commuters between Washington, D.C., and Reston, Va. Measuring equipment included a constant flow sampler pump, a dosimeter, and a readout device. Seat placement of bus and automobile commuters varied but was more often in the rear, an area characterized as possibly having higher CO concentrations. Thirty-seven runs between the two cities were made, 18 in the morning and 19 in the afternoon. Of 40 testing hours, 25 hours were on parkways and suburban streets and 15 hours were in the city. The mean CO concentration in buses was 13.1 ppm;

that in automobiles was 13.8 ppm. Air-conditioned buses averaged 60% higher CO concentrations than nonair-conditioned buses. Ambient concentration levels averaged 3.5 ppm in the city. No relation between ambient levels and interior concentrations in vehicles was discerned. Findings indicate that commuter CO exposure is considerably higher than can be estimated from ambient readings.

ENGINE REPAIR: A MESSAGE FROM JOAN CLAYBROOK

The public's disenchantment with and distrust of the automobile repair industry is addressed. In the wake of escalating prices for gasoline, more complex engines and air pollution devices, higher priced cars, and extended and costlier car financing, consumers find themselves less able to cope with the expense of owning and operating a car. To achieve the best possible fuel efficiency, consumers may find it necessary to spend more money on maintenance. It is estimated that owning and operating vehicles costs Americans about $160 billion yearly, more than income spent on clothing and medical care. Approximately half of this amount is spent for gasoline and oil, repairs and maintenance, insurance, parking, and tolls. About $50 billion involves repair and maintenance work, with $20 billion lost to fraudulent practices by the automobile repair industry and poor automobile design. There is a threatening shortage of qualified mechanics. It is suggested that manufacturers meet their responsibility in training mechanics properly, that engineers and manufacturers pay more attention to designing cars which are easy to service, that independent garage owners have access to service bulletins of manufacturers, that cars be designed to require fewer special tools for repair, and that consideration be given to government regulation or licensing of mechanics.

CARS THAT DON'T PROTECT YOU IN A CRASH

The design of safety features and technology by automobile manufacturers in the United States is explored, the primary issue being the number of Americans who are injured or killed in crashes. Reasonable estimates indicate that every 1,000 vehicles will be involved in 2,000-3,000 crashes that will kill more than three people and injure more than 300. Some major automotive companies are changing their position on motor vehicle safety, and work is progressing on automatic (passive) crash protection systems. These systems will give superior protection in frontal crashes at speeds greatly in excess of the 30-mph crash testing speed required by a Federal standard that becomes effective in 1981. A major problem is how to encourage the public to purchase and use seat belts. Polls show that the public wants to improve automobile safety. Some judicial decisions have favored the delegation of crash-injury protection to manufacturers. Instead of safety, what is sold too often is erroneous information about life-saving technology. Motor vehicle manufacturers need to comment more constructively on government proposals to reduce crash-injuries, to propose Federal motor vehicle safety standards, to show leadership in developing vehicles for safety research, and to exceed Federal minimum motor vehicle safety standards.

SAFETY EFFECTIVENESS EVALUATION OF THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION'S RULEMAKING PROCESS. VOL. 1 -- CASE HISTORY OF FEDERAL MOTOR VEHICLE SAFETY STANDARD 121: AIR BRAKE SYSTEMS

A historical review of the Federal Motor Vehicle Safety Standard (FMVSS) 121, Air Brake Systems, is presented. The standard, issued by the National Highway Traffic Safety Administration (NHTSA) in 1971, specifies air brake system performance requirements for trucks, buses, and trailers. Much of the controversy surrounding the standard involves the use of antilock devices (computerized modules) which were designed to detect wheel skidding during the braking process and to modulate brake pressure to prevent skidding. The historical review is intended to provide a factual account of rulemaking activities associated with FMVSS 121 and to aid in a subsequent safety effectiveness evaluation of the NHTSA rulemaking process.

AN EVALUATION OF PROBATION-BY-MAIL AS AN ALTERNATIVE TO MANDATORY HEARING ATTENDANCE FOR NEGLIGENT OPERATORS

Traffic safety effects of probation by mail were compared to those of individual hearings for 13,899 California drivers whose conviction records placed them at or near the negligent operator level. Of all drivers, 44% or 6,148 fell into the group with high accident risk; these individuals were eliminated from the population of drivers eligible for probation by mail. Remaining subjects were assigned to the probation by mail group (3,883 persons) or to the individual hearing group (3,868 persons) according to the terminal digit of their driver's license number. There were no significant differences in subsequent accident records of the two groups. Drivers in the probation by mail group had significantly more convictions, with a resultant increase in probation violator hearings. Drivers screened as high risk who received the standard hearing did not differ significantly in subsequent accidents or convictions from nonhigh-risk drivers who received a hearing. No evidence was found to indicate that minimizing the number of in-person contacts between negligent operators and driver improvement analysts adversely affected traffic safety. In a closely related study of no-action hearings, there was no evidence that the hearing without probation had a detrimental effect on traffic safety. Because there are no clear-cut accident effect differences between probation by mail and no-action hearings and since probation by mail results in greater budgetary savings, its implementation is recommended.

RISK ANALYSIS IN MAINTAINABLE DESIGNS

The impact of availability and maintainability on management decisions is evaluated within the context of risk analysis. There has been increased utilization of risk analysis to assess reliability and safety considerations in design and management decision processes. A primary business objective is to gain customer acceptance by satisfying product availability criteria. This can be attained by providing highly reliable and/or easily maintainable products. In the design philosophy where a highly maintainable design is the best alternative, risk analysis becomes an important tool in assessing the risk of down time and the risk associated with maintenance actions. Consumerism trends indicate that many individuals maintain their own vehicles. Due to government emission and energy regulations, new design features are being introduced. The goal of developing automobile systems that can be easily maintained without jeopardizing the safety of maintenance personnel can be achieved by establishing mean-time-to-repair criteria and conducting risk analysis studies to assure that maintenance actions pose minimum risk. An illustrative example of risk analysis in headlamp replacement is presented.

SYMBOL SIGNS 2: THE DEVELOPMENT OF PASSENGER/PEDESTRIAN ORIENTED SYMBOLS FOR USE IN TRANSPORTATION-RELATED FACILITIES. FINAL REPORT

As a supplement to 34 passenger and pedestrian symbols designed in the original study for use in transportation-related facilities 16 more have been developed. The project was intended to produce a consistent and interrelated group of symbols that will bridge the language barrier and simplify basic messages at domestic and international travel facilities. The symbol development process has attempted to take full advantage of widely recognized existing symbol concepts and to introduce new symbols only where no satisfactory concepts are available. A detailed description of procedures used to create symbols and suggestions for symbol use are presented under headings of inventory, analysis/evaluation, recommended symbols, and guidelines.

CARGO SECURITY LITERATURE SURVEY

An annotated literature review focuses on cargo theft and pilferage losses in transportation. A major goal of DOT is that goods in U.S. commerce flow arrive at the destination intact, on time, at minimum shipper costs, and with a reasonable carrier profit. By the establishment of an effective cargo security system, transportation management can eliminate, or at least decrease, theft and pilferage losses, can increase profits, can provide more reliable and efficient service, and can make goods available at lower costs. Cargo security is the joint responsibility of shippers, carriers, and receivers. The magnitude of the overall cargo security problem is surveyed in concept. Problems and countermeasures associated with four transportation modes (motor, air, railroad, and water) are covered. Transportation cargo security conferences held to address these problems are noted and a source index to the literature is included.

PASSIVE RESTRAINTS FOR AUTOMOBILE OCCUPANTS--A CLOSER LOOK. REPORT TO THE CONGRESS BY THE COMPTROLLER GENERAL OF THE UNITED STATES

Comments are offered by the Comptroller General on the Dept. of Transportation's (DOT) requirement for passive restraint systems for front-seat occupants in all new cars manufactured after Sep 1, 1983. The two systems under consideration are air bags and automatic seat belts. DOT estimates that passive restraints will prevent about 9,000 traffic deaths and 65,000 serious injuries annually and indicates that the use of sodium azide as the generator of gas for air bags will pose no unmanageable major health, safety, and environmental problems. The department also states that passive restraints can be installed at a reasonable cost and that the cost of such systems will be more than offset by insurance savings. Because of the potential danger for out-of-position occupants, the Comptroller General recommends that additional testing of passive restraints be conducted by the National Hwy. Traffic Safety Administration. It is further suggested that actual experience with passive restraints be evaluated and that the Environmental Protection Agency (EPA) and the Departent of Labor give high priority to assure research on health and safety risks in the production and disposal of sodium azide. Appended are an automobile passive restraints survey of insurance companies and comments by the Dept. of Transportation, Dept. of Labor, and the EPA.

SPEED ADVISORY INFORMATION FOR REDUCED VISIBILITY CONDITIONS. FINAL REPORT

A project was conducted to develop preliminary design specifications for a speed advisory system applicable during periods of reduced visibility (fog). Needed facilities, equipment, and proce-ures were developed to conduct controlled experiments under arying levels of fog density. A series of interrelated experiments was conducted to identify optimum advisory information sign messages and speed values) and the number, location, and nterconnection between signs which would result in the smoothest traffic flow. Based on information from these experiments as well as pertinent literature, preliminary specifications were developed for a full-scale speed advisory system usable on public highways. The interrelated experiments involved six separate studies: determining speeds drivers normally follow at varying levels of reduced visibility with no special signing; determining which of three major percentile speeds (15th, 50th, and 85th) would produce the smoothest traffic flow when used as a posted speed; identifying driver response when other vehicles are present on the highway under reduced visibility conditions; investigating the effect of different types, amounts, and display characteristics of advisory signing; exploring the utility of centerline and edgeline delineation; and determining the effect of unreliable information presentation by advisory signing systems. Forms and procedural information relevant to the project are appended.

A SURVEY OF PERSONS ARRESTED FOR DRIVING UNDER THE INFLUENCE IN THE DISTRICT OF COLUMBIA

A sample of 225 prosecution reports for persons driving under the influence (DUI) of alcohol or drugs in Washington, D.C., was selected for this survey. Reports were obtained through a computer list of all police radio runs for driving under the influence from Jan 1 through Aug 31, 1978. Blood alcohol content (BAC) of apprehended persons was studied to determine consumption patterns of various age groups. Data were obtained on State of residence, race, automobile ownership, attitudes, type of alcohol consumed, consent to test for alcohol content, type of vehicle operated, time of arrest, arrests by day of the week, age, location of arrests by police district, and sex. Among the findings are: the largest percentage of persons arrested for DUI were 31-35 and 20-25 years-of-age; 58.9% of the 20-25 age group were white (in a predominantly black population); early morning hours accounted for the largest number of DUI arrests, and most of these occurred on weekends; most persons arrested for DUI attracted police attention by committing another traffic violation (driving on the wrong side of the street, not maintaining the proper traffic lane); there is direct correlation between weekend DUI arrests and accidents caused by drunk drivers; older age groups recorded higher BAC'S than younger groups; and traffic fatalities involving drunk drivers follow the time-of-day and weekend patterns established by arrests and traffic accidents.

GOVERNMENT EFFORTS TO REGULATE HEAVY TRUCK BRAKING. RESPONSE TO ADVANCE NOTICE OF PROPOSED RULEMAKING: AIR BRAKE SYSTEMS

Response of the University of Michigan's Highway Safety Res. Inst. (HSRI) to the National Highway Traffic Safety Administration (NHTSA) proposed regulation of air brake systems for heavy trucks is presented. Federal Motor Vehicle Safety Standard 121 was implemented by the NHTSA in 1975 to regulate the braking performance of heavy trucks. To assess the impact of this standard, the NHTSA sponsored a 1976-1977 HSRI monitoring study of accidents involving heavy trucks built before and after the standard was enacted. Findings showed that accident rates of trucks complying with the standard were not significantly lower than those of prestandard trucks. The 1979 Advance Notice of Proposed Rulemaking reflects concern that trucks be directionally stable and controllable while braking at deceleration levels necessary to comply with stopping-distance requirements. The HSRI response covers issues associated with the establishment of good braking performance (normal braking situations versus minimum stopping-distance requirements, compromises between braking and stability, and one standard for all commercial vehicles versus the variety of vehicle configurations in use). HSRI comments specifically address four questions: whether requirements of Standard No. 121 should be retained or suspended, and whether these requirements, without the presence of an antilock system, compromise the stability of heavy commercial vehicles; whether a 60-mph stopping-distance requirement should be reinstated in order to prevent the depowering of brakes; whether different stopping-distance requirements should be considered for various test conditions; and whether standards should allow the demonstration of compliance using test procedures which permit wheel lockup as long as the vehicle can be retained within a 12-foot lane. It is considered that issues inherent in regulating heavy truck braking are similar to those encountered in developing other standards to improve automotive safety, fuel economy, and exhaust emissions.

NONCOMPLIANCE WITH HAZARDOUS MATERIALS SAFETY REGULATIONS. SPECIAL STUDY

The National Transportation Safety Board investigated eight serious transportation accidents that involved hazardous materials in transit. Accidents occurred in air, rail, and highway carrier operations. Noncompliance with hazardous materials safety regulations was found in such areas as packaging, labeling, recordkeeping/documentation, and quantity limits. A review of published reports and information about compliance with hazardous materials safety regulations elicited little useful data, since none of the literature discussed reasons for noncompliance. Information was obtained by questionnaire from 11 Federal agencies involved in establishing or maintaining complaince. Interviews were conducted nationwide with about 100 persons in the transportation industry, including shippers, freight forwarders, crating companies, railroads, air carriers, steamship companies, truck lines, and local delivery firms. These interviews provided case histories of actual experience with hazardous materials shipment problems and reasons for noncompliance with regulations. Government and industry agreed on the perceived reasons for noncompliance: complexity and incomprehensibility of regulations; industry interrelationship complexities; economic pressures; unawareness of regulations; lack of training for inexperienced personnel; and indifference. Four recommendations are offered to reduce noncompliance: to expedite the ongoing DOT program of evaluating every hazardous materials safety regulation, to publish nonemergency amendments to regulations on a regular basis, to expand the Materials Transportation Bureau compliance program, and to expand the hazardous materials regulations compliance assurance program. Additional information on accidents involving hazardous materials and the compliance issue is appended.

TEENS, DRUGS AND ALCOHOL: ON THE ROAD AGAIN

The relation between teenage drug and alcohol use and driving is considered. Government estimates indicate that 3,932 drinking drivers between 15-20 years of age were involved in fatal motor vehicle accidents during 1977 in which 4,657 persons died. Both the National Inst. on Drug Abuse and the National Hwy. Traffic Safety Administration suspect that increased use of drugs other than alcohol adversely affects traffic accident statistics. A 1977 survey of high school seniors showed that 6 of every 10 seniors had used some type of illicit drug. Other than alcohol and nicotine, marijuana was the most widely used. In a 1977 Gallup poll, most of the teenagers asked about their involvement in accidents thought the reason was drinking, drugs, or reckless driving. Research has proven that marijuana adversely affects driving ability immediately after use and increases the user's chance of being involved in an accident. Driver simulator studies show that although marijuana does not affect a driver's visual search ability, the drug does alter a driver's ability to coordinate visual searching with vehicle control. Also, drivers under the influence of marijuana are usually unaware of impairment. Many young people do not understand how much alcohol they can consume before driving ability is impaired, and do not perceive serious consequences in getting stopped by police for the possession of alcoholic beverages. One study demonstrates that teenagers perceive less danger in driving after marijuana use than after alcohol consumption. The importance of teenage drug education programs is stressed. In a separate section, an example is given of increased insurance rates for persons convicted of driving under the influence of alcohol or drugs.

METABOLIC HEAT RETENTION AND THE VEHICLE OPERATOR

Comparative heat flux ratings of materials used in automotive seat fabrication were derived to provide information on physiological changes associated with minor heat stress. Because heat stress and metabolic heat retention are major contributing factors to discomfort, fatigue, reduced visual acuity, and performance decrements, trim materials and other constituents of seating devices were studied to evaluate their effect on heat dissipation. Forty-five trim cover materials, 16 trim pads, and five foam cushion pads were examined for impedance to body heat loss by evaporation, conduction, convection, and radiation. The tests were designed to determine the rate per unit of surface area at which heat was transferred through materials. Metabolic retention during relatively high environmental temperature contributed to increased orthostatic intolerance, discomfort, and reduced performance levels. Inappropriate seat trim cover materials added to the vehicle operator's metabolic heat retention problem. It was determined that metabolic heat must be dissipated from the body area in contact with the seat, especially when air conditioning is not available. Trim cover material selected for use in body contact areas must have a high index of "breathability" or a high heat flux value. Recommended heat flux values are noted; the minimum desirable value was established as 24 BTU/sq ft/hr.

INVOLVEMENT OF SUSPENDED/REVOKED DRIVERS IN TRAFFIC CRASHES: A STATEMENT OF THE PROBLEM. GUIDELINES FOR MOTOR VEHICLE ADMINISTRATORS

A study was conducted by the National Hwy. Traffic Safety Administration to determine if drivers whose licenses are suspended or revoked (S/R), and who continue to operate vehicles, are involved in more traffic crashes, and particularly in more fatal car crashes, than the general driving population. Findings revealed that S/R drivers are over-represented in fatal crashes and are probably over-represented in all crashes. S/R drivers had a high incidence of reported drinking (alcohol) in fatal crashes, and S/R drivers were more frequently male than female. The largest target group included males between 20-34 years of age who were over-represented in fatal crashes by about 50%. Uniformity in traffic data reporting by states is lacking. More information is needed on the percentage of S/R drivers in the general driving population at a given time. Suspension and revocation for financial responsibility reasons does not necessarily indicate an unsafe driver. S/R drivers must be viewed in terms of the total system and how they can be effectively treated. Recommendations to strengthen state programs focus on the accuracy and completeness of data on S/R drivers, the development of effective ways to cope with the problem of S/R drivers who continue to drive, the prosecution of drivers, the filing of charges, the probability of S/R drivers being detected, and making the sanction for S/R driving appropriate to the offense. Appended are a description of a traffic enforcement/driver control system in California and tabular data.

AUTOMOTIVE MANUFACTURING ASSESSMENT SYSTEM. VOL. 2: PRODUCT SCHEDULES OF ENGINE/DRIVETRAIN COMBINATIONS. FINAL REPORT

Areas of research involved in evaluating industry's capability to produce fuel efficient vehicles are documented. Engine-driveline changes are considered as an important contribution to fuel economy and the meeting of emission standards. Through extensive synthesis of vehicle specifications and other data, chronological presentations were developed to illustrate engines and transmissions in production, engine/transmission and model/engine combinations, and automatic vs. manual transmission availability. Also shown are the progression of engine/driveline changes from 1975 through 1978; the correlation of these changes with new vehicle introductions; the restrictions on available drivetrain options due to emission requirements; and technological improvements including dieselization, fuel metering, lock-up torque converters, and front-wheel-drive. Methodology is described; summary data and commentary for General Motors, Ford, Chrysler, and American Motors Corp. are included, with supporting detailed information (Engine/Driveline Product Schedules) in the appendices.

AUTOMOTIVE MANUFACTURING ASSESSMENT SYSTEM. VOL. 4: ENGINE MANUFACTURING ANALYSIS. FINAL REPORT

Areas of research involved in evaluating industry's capability to produce fuel efficient vehicles are documented. An analysis of automotive engine manufacturing, conducted to determine the impact of regulatory changes on tooling costs and the production process, is presented. The 351W CID V-8 engine at Ford's Windsor No. 1 Plant was the subject of the analysis. A review of plant history and its product is presented, along with an analysis of manufacturing operations, including material and production flow, plant layout, machining and assembly processes, tooling, supporting facilities, inspection, service and repair. An assessment of the impact on manufacturing methods and cost due to four levels of product change intensity is given. Machines and facilities are illustrated in photographs and diagrams.

THE ROLLING RESISTANCE OF PNEUMATIC TIRES. FINAL REPORT

Important variables affecting passenger car tire rolling resistance are identified. The influence of speed, load, and inflation pressure is discussed, and test data are presented that encompass a wide variety of tires (bias and radial) over a range of rim diameters and tire aspect ratios. Measurements of tire rolling resistance are given, along with equations for converting rolling resistance obtained on drums to equivalent values on the road. Mechanical parameters of tire rolling loss are considered in relation to fuel consumption. Measurement methods and data reduction in rolling loss measurements are appended.

REVISION OF NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION) CURRICULUM PACKAGES. FINAL REPORT

Revision of three National Hwy. Traffic Safety Administration (NHTSA) curriculum packages for emergency medical techicians (refresher, dispatching, and crash victim extrication courses) is discussed. Each of 16 curriculum packages was evaluated and ranked according to 10 criteria devised by the contractor and the NHTSA, and three packages were selected for revision. General editorial and stylistic changes were made. Other revisions directed at particular needs of individual packages included the updating of content and the improvement of teaching effectiveness. Field trials of refresher and crash victim extrication packages were conducted, and packages were revised on the basis of findings. Information on responsibilities and knowledge required of emergency medical technicians and the field test evaluation forms are appended.

REPORT ON REQUESTS BY GENERAL MOTORS AND FORD TO REDUCE FUEL ECONOMY STANDARDS FOR MY (MODEL YEAR) 1981-85 PASSENGER AUTOMOBILES. FINAL REPORT

The National Hwy. Traffic Safety Administration (NHTSA) issued 1981-1984 Fuel Economy Standards for Passenger Automobiles in June 1977. In December 1978, General Motors and Ford began claiming that reduced standards would slow the rate of car price increases and therefore save consumers money. The cost-benefit analysis encompassed such factors as oil consumption and prices, the balance of trade, national security, technology assessment, consumer prices and benefits, consumer net benefits, and fuel conservation. Emission requirements were also addressed. After a review of information on which General Motors and Ford claims were based, the NHTSA concluded that the initiation of rulemaking to reduce standards was not warranted.

TRUCK TIRE CORNERING AND BRAKING TRACTION STUDY. FINAL REPORT

Twenty-four pairs of truck tires were tested for braking and cornering traction on two wet pavements at speeds of 40 and 55 mph. Locked wheel braking force coefficient, peak braking force coefficient, and peak lateral force coefficient were measured. The 24-pair sample was used to predict the traction performance of the truck tire population. Comparisons were made between truck tire and automobile tire populations, and correlations between various traction properties of truck tires were computed. Variability between "identical" tires in traction performance was predicted. The traction performance of tire cornering properties in accident avoidance is discussed.

CONSUMER BEHAVIOR TOWARDS FUEL EFFICIENT VEHICLES. FINAL REPORT

Results are presented of a study directed toward anticipating consumer behavior toward motor vehicles redesigned to meet Federally-legislated automotive fuel economy standards. Automotive design changes already being implemented include weight reduction, reduction in engine size, and the introduction of diesel engines. The results are based on five different research approaches: focus group interviews, a literature review of existing consumer research, further analysis of previously collected data sets, scenario analyses by experts familiar with the auto market, and examinations of time-series data. A general resistance to government regulations was found within all market segments, but specific attitudes towards automotive fuel economy rules differ systematically by vehicle market segment. Small-car drivers tend to be open-minded, but large-car and light-truck drivers believe that vehicle downsizing is leading to a noticeable deterioration in motor vehicle quality. Negative reaction to future fuel-efficient vehicles is strongly influenced by dissatisfaction with the reliability and durability records of some existing domestic subcompact cars. Evidence suggests that light-truck drivers are well satisfied with their vehicles because of their versatility, fuel economy, durability, safety, ease of maint nance, and interior space.

LIGHT DUTY TRUCK CHARACTERISTICS, HISTORICAL DATA BASE. FINAL REPORT

Data concerning physical, operating, performance, and mark characteristics of light-duty trucks for model years 1972 an 1975-1977 are compiled. The data are stored on tape in th computer system of the Transportation Systems Center, Can bridge, Mass. Information from published and unpublishe sources is provided, with extrapolation and correlations mad when raw data were not available. Vehicles are reported b model year and are grouped by manufacturer using productio volume, model, body type, engine displacement, transmissio and gross vehicle weight class attributes as criteria to sele representative vehicle configurations. Models essentially dupl cated by more than one division of a manufacturer are repr sented by attributes of only one duplicate model. Productio volume for both models is then combined. Characteristics ar documented for vehicles representing total U.S. sales of dome tic and imported light-duty trucks. It is recommended that th data base be expanded to include all years from 1955 to th present, and that further studies include the uses of light truck and types and sizes of loads usually carried, with resultin effects on fuel economy.

THE CAMPAIGN FOR TRAFFIC SAFETY IN PORTUGAL (CAMPANHA DE SEGURANCA RODOVIARIA). FINAL REPORT

Work of the Portuguese Coordinating Committee of the Can paign for Traffic Safety is reported. The campaign involv cooperation between representatives of government and priva agencies; it has the full support of the media. An essenti feature of the campaign has been its effective use of brochure handouts, and posters to inform and motivate the public (exan ples provided, with translation). The coordinating committ realizes that efforts in the field of traffic safety cannot be eval ated solely in terms of accident statistics. It emphasizes th global context of behavioral changes in individuals to mal them respect the rights of others, respect themselves, and che ish the rights they enjoy.

MOBILE ORBIS III SPEED ENFORCEMENT DEMONSTRATION PROJECT IN ARLINGTON, TEXAS: PROGRAM EVALUATION. FINAL REPORT

An evaluation is presented of the Mobile ORBIS III Speed Enforcement Demonstration Project in Arlington, Texas, which detects and photographs speeders (recording speed, time, date, driver, and license). The device was installed in a van and its performance was evaluated at four sites over a 3-month period. Sites were selected to provide data on the impact of the unit in various road environments (rural, residential, urban, and urban thoroughfare) with differing posted speed limits. Each site was evaluated at 25% and 50% enforcement levels. The greatest impact in reductions of percent speeders was realized on urban roads at the high enforcement level, with a general reduction in speeders realized throughout 0.5-mile test segments. Significant but less dramatic reductions were observed at rural and residential sites where the lower enforcement level appeared to be more effective. Speed distribution profile data showed a small decrease in mean speeds at three of the four sites; the impact of the unit lasted for some time after the van was removed from operation. Although an administrative evaluation of the project showed the mobile ORBIS III unit to be less cost-effective than standard patrol techniques, evaluation indicated the unit's cost-effectiveness could be considerably improved with the design and operation of appropriate patrol strategies. Information on statistical analysis techniques and samples of warning and citation letters are appended. It is noted that the National Hwy. Traffic Safety Administration does not support the cost/effectiveness analysis of the report, since the project was not designed for that purpose.

SELECTIVE SURVEY OF THE CAPABILITY OF REPRESENTATIVE AUTOMOBILE REPAIR FACILITIES TO DIAGNOSE AND REPAIR AUTOMOBILES. FINAL REPORT

Automobile repairs were evaluated in seven U.S. cities (Atlanta, Ga.; Philadelphia, Pa.; Miami, Fla.; Nashville, Tenn.; Houston, Tex.; and White Plains and Brooklyn, N.Y.). Project personnel worked closely with the district attorney's office in each city. A reputable repair facility was used as the secure facility, providing inspection space and master mechanics. Sixty-two cars were inspected at secure facilities and documented. Engine and suspension malfunctions were induced into the cars, and the cars were reinspected and repairs documented. Results indicate that 39% of the cars had unnecessary brake, engine, or suspension repair; 20% of the cars did not have induced malfunctions repaired; and 51% of the cars were over-repaired or under-repaired with respect to brakes, engine, or suspension system. A list of candidate agency action items, information on the data reduction procedure, and a detailed list of repairs are appended.

TECHNIQUES FOR PREDICTING HIGH-RISK DRIVERS FOR ALCOHOL COUNTERMEASURES. VOL. 1: TECHNICAL REPORT. FINAL REPORT

The development and testing of predictive models for identifying individuals with a high risk of alcohol-related (AR) crash involvement are described. Six groups of drivers at high risk of AR crashes were identified from a literature review and an analysis of North Carolina accident data: 16-20 year old males; 21-24 year old males; persons with prior driving under the influence convictions; persons with three or more moving violations; persons recently divorced; and persons recently released from prison. A seventh control group represented a one-tenth sample of the general driving population. Using North Carolina data through 1974, predictive models were developed for each group to predict 1975 AR accident involvement proportions for subgroups within each high-risk group. Prospective analysis of predictive capabilities using 1976 car crash data revealed that, in general, models effectively identified driver subgroups with the highest risk of AR crash involvement. Since most information used in model development is available in most government jurisdictions, the models can be adapted for use in other areas. The major drawback to widespread model use is the lack of demonstrably effective countermeasure programs that significantly reduce the rate of AR crash involvement for identified driver subgroups. Appendixes contain the alcohol model study record format, information on predicted probabilities of AR crash involvement, design matrices and model coefficients, and prospective validity test frequency distributions.

WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST VS ROAD LOAD TEST ON 1978 FORD LN600 FLAT BED TRUCK. FINAL REPORT

The preparation and testing procedures are reported for a windshield defrosting and defogging systems test series on light duty trucks. Tests were conducted to evaluate FMVSS 103 under idle and road load conditions at various wind velocities. The vehicle under test was a 1978 Ford LN600 flat bed truck (VIN-N62EVAJ7432). The test equipment included a drive-in chamber, an engine rpm recording and control system, and recording systems for temperature, road load roller speed, and wind velocity. Incorporated into the drive-in chamber were two heat exchangers with blower systems. A pre-cooled solvent was circulated through the heat exchangers to maintain ambient temperature. Ten windshield test patterns were made. Test data sheets, photographs, and an equipment list are provided.

STATE MOTORCYCLE SAFETY ACTIVITIES

Statistical information on state motorcycle safety activities was gathered from several sources, including the Fatal Accident Reporting System, the Federal Hwy. Administration, the National Hwy. Traffic Safety Administration (NHTSA), and state highway safety plans for fiscal year 1979. The report is intended to depict the increasing motorcycle fatality rate and to encourage remedial action. Motorcycle registration increased from 4,964,000 in 1975 to 5,138,000 in 1978 (3.5%), while motorcycle fatalities increased from 3,189 in 1975 to 4,554 in 1978 (4.1%). Miles of travel by motorcycles increased by 1.4% between 1975 and 1978, but the fatality rate per 100 million vehicle miles of travel for motorcycles in 1978 was 19.5, six times that for all other motor vehicles. As states repeal or weaken their helmet laws, increasing numbers of motorcyclists do not wear protective headgear, thus increasing the risk of serious injury or death. Both human and financial costs of motorcycle accidents are high. In an effort to reduce risks associated with motorcycle operation, NHTSA'S motorcycle program emphasizes the need for improved rider education and training, comprehensive licensing and screening procedures, promotion of approved headgear safety aspects, increased conspicuity of motorcycles, and education of other motor vehicle operators to make them more aware of motorcyclists and to recognize motorcyclists' rights. A summary analysis of motorcycle fatalities, fatality rates, registrations, and helmet laws by state is provided. Data on fatalities and registrations, helmet law status, and motorcycle countermeasure activities planned by states and reported in their 1979 highway safety plans are evaluated.

DRIVERS LICENSE SUSPENSIONS FOR FAILURE TO APPEAR IN COURT

A review is made of the status of state laws which provide for administrative action against the drivers license of a person who fails to appear in court to answer a traffic charge. Three different approaches are described. The unilateral approach involves suspension of the driving privilege of the person failing to appear, and is not based on any agreement with other states, although it can be applied to nonresidents. The driver license bail approach refuses to return the license which the arrested person has deposited in lieu of bail, on failure to appear; this is usually limited to residents. The reciprocal approach involves a bilateral and multilateral agreement with other states, usually providing that if a resident of one state is arrested in another he will be released upon signing his promise to appear; if he fails, the home state agrees to suspend his driving privilege until he does. The Commentary analyzes state laws following these approaches, evaluating some of the strengths and weaknesses of each, but limiting itself to those laws which address the problem through administrative action against the driving privilege.

DEVELOPMENT OF A MOTOR VEHICLE MATERIALS HISTORICAL, HIGH VOLUME INDUSTRIAL PROCESSING RATES COST DATA BANK (LIGHT TRUCK). FINAL REPORT

In a study designed to identify and establish a Motor Vehicle Materials High-Volume Industrial Processing Cost Data Bank for a light truck, the following two methods were used: a micro-analysis, in which costs were generated using the automotive industry type estimation techniques, and a macro-analysis, in which costs were determined for a study of 8 years of an automotive corporation's historical financial records. In the micro-analysis method, a 1978 light truck was dismantled, components and subassemblies were analyzed in detail to determine the weight, manufacturing method, and estimated manufacturing cost associated with each item. From the basic data, other categorical costs were estimated, such as a total cost for each item and a cost per pound. The various items were grouped into several levels of assemblies on a basis of practiced industry groupings to produce total cost categories of the complete vehicle. The macro-analysis produced data for substantiating the micro-analysis data. The program developed technical data in manual chart form applicable to a computerized cost data bank, that can be used as a reference base for implementing a simplified building-block estimation system to facilitate the estimating task, to establish standardized across-the-board estimation procedures, and to generate credible consumer cost estimates for proposed rule-making actions. The application of this data to other vehicles should be made only after studies indicate a similarity in design. The micro-analysis cost data, macro-analysis study, and photographs of components of the specimen vehicle are appended.

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, JULY 1, 1979 TO SEPTEMBER 30, 1979, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS

A quarterly summary report is given on defect campaigns conducted by domestic and foreign manufacturers. Following a summary of tabulations of motor vehicle safety defect recall campaigns, information is given on domestic and foreign automobile manufacturers recall campaigns, including the NHTSA identification number, date of company notification, make, model, model year, a brief description of the defect and the manufacturer's corrective action, number of pages on file, and number of vehicles recalled. The recall campaigns involve passenger cars, station wagons, motorhomes, travel vans, trucks (light, medium and heavy), fire trucks, diesel trucks, transit coaches, buses and minibuses, motorcycles, mopeds, United Parcel Service vehicles, and tractor/trailers. Similar information is presented on campaigns by manufacturers of equipment and tires. The status of domestic and foreign campaigns completed as of 30 June 1979 is included.

ACCIDENT INVESTIGATION STUDIES. STAGED REAR IMPACT COLLISIONS. FINAL REPORT

Collisions reported in this study were performed under Contract DOT-HS-8-01886, "Test and Evaluation of Fuel System Integrity in Rear Impact Collisions," and establish data on rear impacts, a mode for which little data are presently available. The information includes documentation of trajectory, residual crush, braking and steering forces, and tire marks for each vehicle in each test. Pre- and post-test photographs are provided; the appended test results provide a staged collision trajectory and damage data summary for each test, together with the data sheets used in its generation.

UNDERRIDE GUARD DESIGN FEASIBILITY STUDY. FINAL REPORT

A parametric design analysis was performed to define the characteristics of protection devices which could be incorporated on the rear end of highway trailers in order to avoid automobile vehicle underride in a crash situation. The study was particularly concerned with the effect of weight and cost of the devices as they relate to parameters such as load capacity, guard height, restriction of the rear sliding bogie movement, and energy attenuation. Four separate design concepts were developed and compared on the basis of weight, cost, and slider restriction. Included were rigid as well as energy absorbing design approaches. Results have generally indicated that the energy absorbing guard approach has the best potential from a weight efficiency standpoint, and that significant modifications will be required to the trailer structure to absorb the impact loads under consideration. Further analysis of the trailer structure response and required reinforcement is recommended; a mass model analysis similar to that developed by National Hwy. Traffic Safety Administration and employed by The Budd Co. in assessing automobile crashworthiness is suggested to determine the interaction between the vehicles in the crash event. Recommendations for further study include the degree and nature of damage which would be sustained by plastic deformations within the trailer structure and their effect on the vehicle, and the effectiveness and weight of energy absorbing guards. A program of scale model and full scale testing is also recommended. Background information on scale model techniques as employed by the Budd Co. Technical Center is appended, as are weight tabulations.

REPEATABILITY OF VISIBILITY TESTS. FINAL REPORT

Tests were carried out to provide information on current production vehicles with regard to repeatability in making measurements of obstructions to visibility and of the fields of view through the rear view mirror system. Three tests were made on each vehicle: International Harvester Diesel Tractor Transtar 4300, Ford Econoline Van E-100, and AMC Concord 4-Door Sedan. Tests were conducted as prescribed in the National Highway Traffic Safety Administration's proposed standards on "Fields of Direct View" (Docket 70-7, Notice 5), and "Rearview Mirror Systems" (Docket 71-3a, Notice 4). For the rearview mirror systems, only the ambinocular fields of view were measured. In general, there was good repeatability on the direct fields of view measurements. Minor difficulties were encountered in positioning some of the mirrors repeatably. Test procedures are appended, followed by the data on the three vehicles, with photographic documentation.

TRAINING PROGRAM FOR ACCIDENT INVESTIGATION AND CODING IN THE NATIONAL CRASH SEVERITY STUDY. FINAL REPORT

An accident investigation and coding training program for personnel in the National Crash Severity Study is described. A two-day session for working investigators in that study was designed to eliminate inconsistencies between teams. These ranged from a lack of uniformity in field collection of vehicle and scene data through poor photography, inadequate number or type of photographs, incorrect measurements, inconsistencies in rating injury and Collision Deformation Classification (CDC), and improperly completed interviews. Major emphasis in the program was on scene investigation and documentation, vehicle evaluation and documentation, rating the CDC and Abbreviated Injury Scale/Occupant Injury Classification (AIS/OIC) injury scales, photography, and the use of the CRASH program. Two training films, one on scene investigation and one on vehicle evaluation, were also produced. In evaluating the session, the majority of trainees felt the training should have been held earlier in the program, and that similar courses as refreshers would be beneficial. Topics thought to be most useful, in the order mentioned, were vehicle evaluation and measurement, Calspan Reconstruction of Accident Speeds on the Highway (CRASH), photography, interviewing, CDC, injury coding and scene measurement. Lists of instructors and attendees are attached, and the program syllabus is appended.

SEAT BELT PERFORMANCE OF MANUAL AND AUTOMATIC SYSTEMS INSTALLED IN THE GM CHEVROLET CHEVETTE AND THE VW RABBIT

A review of test data obtained from both manual and automatic seat belt equipped Chevrolet Chevettes and VW Rabbits indicated that the chest accelerations of both driver and front seat passenger, when restrained by either system, were comparable. However, the Head Injury Criteria (HIC) for both driver and passenger restrained by the automatic system were about half those of the manual system; the forward motion of the dummy restrained by the automatic seat belt was much less than that of the dummy restrained by the manual belt. This can be partly ascribed to the difference in belt length; the automatic belt system has the potential of reducing belt stretch to less than half that of the manual system, greatly improving head protection. The other consideration, absence of lap belt in the automatic system, permits the occupant to remain upright instead of jackknifing about the lap belt. Results were similar in both Chevette and VW Rabbit tests, indicating that their automatic belt systems have the potential of offering improved protection over current active belt systems.

THE EFFECT OF USING A "TOWAWAY" THRESHOLD IN STUDYING TRAFFIC ACCIDENTS. FINAL REPORT

The Restraint Systems Evaluation and the National Crash Severity Study utilized a "towaway" threshold for inclusion of accident vehicles in their samples; this will be the major criterion for much of the National Accident Sampling System as well. In order to demonstrate the possible effects of biases in a data base restricted to towaway accidents, an accident file containing both towaway and non-towaway accidents is required, along with information on vehicle drivability; the 1976 North Carolina and 1975 New York accident files meet these criteria and were selected for use in the analysis. Data sources and analysis procedure are discussed, as well as principal findings and their implications. The independent variables most closely associated with post-crash vehicle driveability are identified, and accident and injury characteristics, along with seat belt usage and effectiveness estimates, are compared as a function of the sampling criterion. Compared with all accidents, injury rates are overestimated in towaway accidents, while restraint usage and belt effectiveness are underestimated. Results indicate that there are differences between accident data based on a towaway criterion and those based on a typical statewide reporting threshold (e.g., personal injury and/or property damage exceeding $200). Most configurations such as high speed, front-end impacts, which result in more severe accidents would be overrepresented in such data bases; this should be accounted for when noninjury or minor injury accidents are the focus of a study. When the injury criterion is relatively serious, the towaway sample will exclude only approximately 1.5% of the fatalities and only 4.6% of the serious injuries.

SOCIAL CONSEQUENCES OF ACCIDENTS. FINAL REPORT

Seven seriously injured traffic victims and their families were interviewed in order to have them describe, in their own words, the long-term personal and social consequences of serious traffic accidents. Taped interviews, usually lasting two hours, were held in the respondents' homes, the discussion concerning the financial, psychological and family consequences of their injuries. There was great difficulty in contacting suitable informants. In future studies, access to medical records would provide a more valid assessment of physical trauma and a more reliable means of contacting victims who have moved since the accident. The Abbreviated Injury Scale and the Injury Severity Score are inadequate indicators of the long-term personal and social consequences resulting from serious traffic injuries. The victim with the lowest ISS rating appeared to have suffered the most severe consequences from her injury. Most respondents indicated a fatalistic attitude towards the use of seat belts. A modest study of the effects of spinal cord injuries is recommended, as well as independent interviews with other family members. It is also recommended that the use of AIS ratings for predicting social consequences be supplemented by additional information such as the age, sex and occupation of the accident victim.

AUTO CRASHES: THE REPERCUSSIONS FOR THE AMERICAN FAMILY

Human consequences of traffic accidents for victims and their families are explored in order to educate the public about the seriousness of the problem. Seven severely injured victims of traffic accidents in two California counties (Alameda and Contra Costa) were interviewed to elicit data on long-term personal and social consequences of serious traffic accidents. An attempt was made to conduct interviews in an informal and relaxed atmosphere, usually in the person's home. Interviews lasted about two hours, and respondents were offered payment of $8.00 per hour. Victims talked extensively about the impact of accidents on such areas as work, finances, and recreation. They were occasionally reluctant to discuss the impact on such personal and sensitive areas as emotional problems. Four victim interviews are reviewed in detail, and a brief examination of the other three interviews is provided. Considerations for additional study are cited.

EMERGENCY MEDICAL SERVICES: FIRST RESPONDER TRAINING COURSE. COURSE GUIDE

This updated course guide is an aid to the administrator in planning and managing a training program in emergency medical care for those who are apt to be the first persons responding to an accident. The course objective is to improve the quality of emergency medical care rendered to victims of accidents and illnesses. The three main sections of the course guide focus on the instructional program, course planning considerations, and course management and evaluation. No prior training or experience in the emergency medical care field is required of the course applicant. Upon successful completion of the program, the trainee will be proficient not only in providing basic emergency care but also in taking any actions necessary to minimize patient suffering and to prevent further injury. The instructional strategy is one of learning by doing. Each lesson provides for practice of the skills and knowledge covered in that lesson, wherever possible. In addition, special review and practice sessions are incorporated, and the course design provides for review and integration of course contents. The course consists of 28 lessons (including one optional lesson) involving a minimum of 40 hours in classroom and field training.

EMERGENCY MEDICAL SERVICES: FIRST RESPONDER TRAINING COURSE. INSTRUCTOR'S LESSON PLANS

These updated lesson plans contain detailed outlines of course content and guidance for teaching each course lesson of a training program in emergency medical care for those who are apt to be the first persons responding to an accident. The course objective is to improve the quality of emergency medical care rendered to victims of accidents and illnesses. In general, lessons have been designed to be self-contained units. Lesson plans consist of four parts: objectives, requirements, reference(s), and outline. No prior training or experience in the emergency medical care field is required of the course applicant. Upon successful completion of the program, the trainee will be proficient not only in providing basic emergency care but also in taking any actions necessary to minimize patient suffering and to prevent further injury. The instructional strategy is one of learning by doing. Each lesson provides for practice of the skills and knowledge covered in that lesson, wherever possible. In addition, special review and practice sessions are incorporated, and the course design provides for review and integration of course contents. The course consists of 28 lessons (including one optional lesson) involving a minimum of 40 hours in classroom and field training.

EMERGENCY MEDICAL SERVICES: FIRST RESPONDER TRAINING COURSE. STUDENT STUDY GUIDE

This completely revised study guide is a training aid for students enrolled in a training program in emergency medical care designed for those who are apt to be the first persons responding to an accident. The course objective is to improve the quality of emergency medical care rendered to victims of accidents and illnesses. This guide has been prepared to inform the trainee of lesson objectives, coverage, and procedures, and to assist him in acquiring the skills and knowledge required for competent on-the-job performance as a first responder. A section for each course lesson is provided. For lessons in which new skills and knowledge are taught, the following format is employed: introductory paragraph describing lesson purpose and need, objectives, overview of lesson contents, study suggestions, and reference(s) on which the technical content is based. No prior training or experience in the emergency medical care field is required of the course applicant. Upon successful completion of the program, the trainee will be proficient not only in providing basic emergency care, but also in taking any actions necessary to minimize patient suffering and to prevent further injury. The instructional strategy is one of learning by doing. Each lesson provides for practice of the skills and knowledge covered in that lesson, wherever possible. In addition, special review and practice sessions are incorporated, and the course design provides for review and integration of course contents. The course consists of 28 lessons (including one optional lesson) involving minimum of 40 hours in classroom and field training.

HS-900 026

STATEWIDE INSTRUCTOR TRAINING GOAL OF FLORIDA DEPT. OF EDUCATION
HS-026 918

INSULATED

COLD TEMPERATURE TESTS OF HEATED/INSULATED BATTERY FOR AM (AMERICAN MOTORS) GENERAL DJ-5E JEEPS
HS-026 938

INSURANCE

AUTOMOBILE INSURANCE LOSS, COLLISION COVERAGES; THE CONSISTENCY OF THE LOSS EXPERIENCE OF SPECIFIC VEHICLES PRODUCED IN SEVERAL YEARS, 1975 TO 1978 MODELS
HS-026 801

AUTOMOBILE INSURANCE LOSSES, COLLISION COVERAGES; INITIAL RESULTS FOR 1979 MODELS
HS-026 799

AUTOMOBILE INSURANCE LOSSES, INJURY COVERAGES; COMPARISONS OF CLAIM FREQUENCIES OF VOLKSWAGEN RABBITS WITH AUTOMATIC AND MANUAL SEAT BELTS, 1975, 1976, AND 1977 MODELS
HS-026 800

AUTOMOBILE INSURANCE--1978
HS-026 842

INTAKE

FLOW VISUALIZATION STUDY OF THE INTAKE PROCESS OF AN INTERNAL COMBUSTION ENGINE
HS-026 860

INTERACTION

THE INTERACTION BETWEEN ETHANOL AND ANTIHISTAMINES. 1: DEXCHLORPHENIRAMINE
HS-026 838

INTERNAL

FLOW VISUALIZATION STUDY OF THE INTAKE PROCESS OF AN INTERNAL COMBUSTION ENGINE
HS-026 860

LASER DOPPLER ANEMOMETER MEASUREMENTS IN AN INTERNAL COMBUSTION ENGINE
HS-026 859

INVENT

IF WE CAN SEND A MAN TO THE MOON, WHY CAN'T WE RE-INVENT THE CAR? WHAT WILL THE CAR OF THE FUTURE LOOK LIKE?
HS-026 853

INVESTIGATION

ACCIDENT INVESTIGATION STUDIES. STAGED REAR IMPACT COLLISIONS. FINAL REPORT
HS-805 197

TRAINING PROGRAM FOR ACCIDENT INVESTIGATION AND CODING IN THE NATIONAL CRASH SEVERITY STUDY. FINAL REPORT
HS-805 202

INVOLVEMENT

INVOLVEMENT OF SUSPENDED/REVOKED DRIVERS IN TRAFFIC CRASHES: A STATEMENT OF THE PROBLEM. GUIDELINES FOR MOTOR VEHICLE ADMINISTRATORS
HS-804 104

ISSUE

AIR BAGS: A SPECIAL ISSUE
HS-026 925

ITALIAN

ENEL (ITALIAN ELECTRICITY BOARD) EXPERIENCE AND DEMONSTRATION PROGRAMS IN THE FIELD OF ELECTRIC VEHICLES
HS-026 896

JEEPS

COLD TEMPERATURE TESTS OF HEATED/INSULATED BATTERY FOR AM (AMERICAN MOTORS) GENERAL DJ-5E JEEPS
HS-026 938

KEEPING

EFFECTS OF PAVEMENT DELINEATION MARKING ON VEHICLE LATERAL POSITION-KEEPING
HS-026 798

KILLER
HOW WE'LL RUN KILLER TRUCKS OFF THE ROADS
HS-026 830

KM
THE EFFECT OF THE ABSOLUTE SPEED LIMIT OF 100 KM/H ON ACCIDENTS IN VICTORIA [AUSTRALIA]. TECHNICAL REPORT
HS-026 891

KNOCK
LEARNING TO LOVE THE PING [ENGINE KNOCK]
HS-026 793

KRAFTSTOFF
ETHANOL FROM BIOMASS AS AUTOMOTIVE FUEL (ATHANOL AUS BIOMASSE ALS KRAFTSTOFF FUR AUTOMOBILE)
HS-026 884

KUPPLUNGSBETATIGUNG
MECHANICAL BOOSTERS FOR BRAKE AND CLUTCH ACTUATION (MECHANISCHE VERSTARKER ZUR BREMSEN- UND KUPPLUNGSBETATIGUNG)
HS-026 850

LABILE
EFFECT OF LABILE CROSSLINKED SBR (STYRENE BUTADIENE RUBBER) ON PROPERTIES OF RADIAL TIRE COMPOUNDS
HS-026 900

LANGUAGE
VALIDATION COMMAND LANGUAGE (1979 VERSION). FINAL REPORT
HS-026 944

LARGE
CONSIDERATIONS FOR REARVIEW MIRROR SYSTEMS FOR LARGE TRUCKS
HS-026 786

LASER
APPLICATION OF LASER DIAGNOSTICS TO AN INJECTED ENGINE
HS-026 857

GAS VELOCITY MEASUREMENTS OF A MOTORED AND FIRING ENGINE BY LASER ANEMOMETRY
HS-026 861

LASER DOPPLER ANEMOMETER MEASUREMENTS IN AN INTERNAL COMBUSTION ENGINE
HS-026 859

LATERAL
EFFECTS OF PAVEMENT DELINEATION MARKING ON VEHICLE LATERAL POSITION-KEEPING
HS-026 798

LAYOUTS
TORT LIABILITY: SPECIAL PROBLEMS ENCOUNTERED BY HIGHWAY AGENCIES AND CONTRACTORS IN DESIGNING WORK ZONE LAYOUTS
HS-026 937

LEAP
ADAMS CALLS FOR MAJOR LEAP IN AUTOMOTIVE FUEL ECONOMY
HS-026 915

LEARNING
LEARNING TO LOVE THE PING [ENGINE KNOCK]
HS-026 793

LESSON
EMERGENCY MEDICAL SERVICES: FIRST RESPONDER TRAINING COURSE. INSTRUCTOR'S LESSON PLANS
HS-900 026

LEVEL
USER'S MANUAL: FHWA (FEDERAL HIGHWAY ADMINISTRATION) LEVEL 2 HIGHWAY TRAFFIC NOISE PREDICTION MODEL, STAMINA 1.0. FINAL REPORT
HS-026 913

LIABILITY
LIABILITY FOR IMPROPER TRAFFIC SIGNALING, SIGNING, AND PAVEMENT MARKINGS. ABRIDGMENT
HS-026 929

OPTIONAL SAFETY DEVICES: HOW STRICT THE LIABILITY?
HS-026 789

TORT LIABILITY: SPECIAL PROBLEMS ENCOUNTERED BY HIGHWAY AGENCIES AND CONTRACTORS IN DESIGNING WORK ZONE LAYOUTS
HS-026 937

LICENSE
CORRECTION OF LICENSE PLATE SURVEYS FOR SPURIOUS MATCHES
HS-026 815

DRIVERS LICENSE SUSPENSIONS FOR FAILURE TO APPEAR IN COURT
HS-805 118

LIFE
LIFE IN THE SLOW LINE [LINES AT GASOLINE STATIONS]
HS-026 816

LIFESAVER
OPERATION LIFESAVER: A PROGRAM TO REDUCE ACCIDENTS AND DEATHS AT RAILROAD-HIGHWAY CROSSINGS
HS-026 886

LIFT
ELECTRICS INFILTRATE THE RANKS OF LIFT TRUCKS
HS-026 831

LIGHT
DEVELOPMENT OF A MOTOR VEHICLE MATERIALS HISTORICAL, HIGH VOLUME INDUSTRIAL PROCESSING RATES COST DATA BANK (LIGHT TRUCK). FINAL REPORT
HS-805 161

LIGHT AND HEAVY TRUCKS LOSE WEIGHT, GAIN PAYLOAD
HS-026 788

LIGHT DUTY TRUCK CHARACTERISTICS, HISTORICAL DATA BASE. FINAL REPORT
HS-804 787

WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST

VS ROAD LOAD TEST ON 1978 FORD LN600 FLAT BED TRUCK. FINAL REPORT
HS-804 860

WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST VS ROAD TEST ON 1978 CHEVROLET G20 SPORTVAN. FINAL REPORT
HS-804 861

WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST VS ROAD LOAD TEST ON 1977 GMC SIERRA 15 PICKUP TRUCK. FINAL REPORT
HS-804 862

LIGHTER
COMING: LIGHTER COMPONENTS [AUTOMOBILE CASTINGS AND FORGINGS]
HS-026 796

LIKE
IF WE CAN SEND A MAN TO THE MOON, WHY CAN'T WE RE-INVENT THE CAR? WHAT WILL THE CAR OF THE FUTURE LOOK LIKE?
HS-026 853

LIMIT
THE EFFECT OF THE ABSOLUTE SPEED LIMIT OF 100 KM/H ON ACCIDENTS IN VICTORIA [AUSTRALIA]. TECHNICAL REPORT
HS-026 891

LINE
LIFE IN THE SLOW LINE [LINES AT GASOLINE STATIONS]
HS-026 816

RISK ANALYSIS OF AN AUTOMATED ASSEMBLY LINE OPERATION
HS-026 939

LINES
LIFE IN THE SLOW LINE [LINES AT GASOLINE STATIONS]
HS-026 816

LININGS
REFLECTORIZED ROADWAY LININGS CUT HIGHWAY ACCIDENT, DEATH TOLLS
HS-026 803

LIQUEFIED
COMPUTER MODEL FOR LIQUEFIED NATURAL GAS AND LIQUEFIED PROPANE GAS RISK SIMULATION
HS-026 934

LITERATURE
CARGO SECURITY LITERATURE SURVEY
HS-026 954

LITTLE
LITTLE CARS: THEIR TIME HAS COME
HS-026 833

LIVES
IMPACT ATTENUATORS SAVE LIVES, VEHICLES
HS-026 804

LN
WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST VS ROAD LOAD TEST ON 1978 FORD LN600 FLAT BED TRUCK. FINAL REPORT
HS-804 860

LOAD
WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST VS ROAD LOAD TEST ON 1978 FORD LN600 FLAT BED TRUCK. FINAL REPORT
HS-804 860

WINDSHIELD DEFROSTING AND DEFOGGING SYSTEMS TEST ON LIGHT DUTY TRUCKS. IDLE TEST VS ROAD LOAD TEST ON 1977 GMC SIERRA 15 PICKUP TRUCK. FINAL REPORT
HS-804 862

LONDON
THE LONDON ELECTRIC DELIVERY VAN ASSESSMENT SCHEME
HS-026 897

LOOK
IF WE CAN SEND A MAN TO THE MOON, WHY CAN'T WE RE-INVENT THE CAR? WHAT WILL THE CAR OF THE FUTURE LOOK LIKE?
HS-026 853

PASSIVE RESTRAINTS FOR AUTOMOBILE OCCUPANTS--A CLOSER LOOK. REPORT TO THE CONGRESS BY THE COMPTROLLER GENERAL OF THE UNITED STATES
HS-026 955

LOOKS
HAZARDS TO CHILDREN IN TRAFFIC: A PAEDIATRICIAN LOOKS AT ROAD ACCIDENTS
HS-026 820

LOSE
LIGHT AND HEAVY TRUCKS LOSE WEIGHT, GAIN PAYLOAD
HS-026 788

LOSS
AUTOMOBILE INSURANCE LOSS, COLLISION COVERAGES; THE CONSISTENCY OF THE LOSS EXPERIENCE OF SPECIFIC VEHICLES PRODUCED IN SEVERAL YEARS, 1975 TO 1978 MODELS
HS-026 801

LOSSES
AUTOMOBILE INSURANCE LOSSES, COLLISION COVERAGES; INITIAL RESULTS FOR 1979 MODELS
HS-026 799

AUTOMOBILE INSURANCE LOSSES, INJURY COVERAGES; COMPARISONS OF CLAIM FREQUENCIES OF VOLKSWAGEN RABBITS WITH AUTOMATIC AND MANUAL SEAT BELTS, 1975, 1976, AND 1977 MODELS
HS-026 800

LOVE
LEARNING TO LOVE THE PING [ENGINE KNOCK]
HS-026 793

LUBRICANTS
THE GREAT DEBATE. SYNTHETIC OILS AND LUBRICANTS, AFTERMARKET OIL ADDITIVES, AND THE "IF" FACTOR
HS-026 912

MAIL

AN EVALUATION OF PROBATION-BY-MAIL AS AN ALTERNATIVE TO MANDATORY HEARING ATTENDANCE FOR NEGLIGENT OPERATORS
HS-026 951

MAINTAINABLE

RISK ANALYSIS IN MAINTAINABLE DESIGNS
HS-026 952

MAINTENANCE

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safety Administration (NHTSA). It is divided into the following sections: Abstract Citations, containing bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-of-context (KWOC) list of words in the title, followed by the full title and HS number (our accession number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Report Number Index. In those months when information on contracts recently awarded is available, a section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technical Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Editor at the address below for inclusion in the collection and abstracting in this publication. Please indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for information. Views expressed are those of the authors and not necessarily those of the Administration. Reference to brand names, equipment, models or companies does not imply endorsement by NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Safety Literature** may be addressed to

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive Engineers, Dept. HSL, 400 Commonwealth Drive, Warrendale, Pa. 15096. Order by title and SAE report number.

TRB: Transportation Research Board, National Academy of Sciences, 2101 Constitution Ave., N.W., Washington, D.C. 20418.

Corporate author: Inquiries should be addressed to the organization listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED BY MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning the maximum amount of brake pedal force that automobile drivers were able to sustain over a period of ten seconds. Subjects were told to apply the brakes in the test car as they would in a panic stop, and to exert as much force as possible on the pedal over the entire ten second test period. A total of 84 subjects were tested, including 42 males and 42 females. The results indicated that there is a wide distribution of values which characterizes the pedal force that the subjects were able to generate. Male subjects produced generally higher forces than did females. Over half the women tested were unable to exert more than 150 lbs. of force with either foot alone, but when both feet were applied to the pedal, force levels rose significantly.

Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflation pressure are deduced by assuming the bias tire as a composite structure of a bias-laminated, toroidal membrane shell and rigorously taking three displacement components into consideration. The point collocation method is used to solve a derived system of differential equations with variable coefficients. It is found that the lowest natural frequencies calculated for two kinds of bias tire agree well with the corresponding experimental results in a wide range of inflation pressures. Results of the approximate analysis show that the influences of the in-plane inertia forces on natural frequency may be considered small, but the influences of in-plane displacements are large, particularly on the natural frequency of the tire under low inflation pressure.

GLOSSARY OF AUTOMOTIVE TERMINOLOGY. SPANISH-ENGLISH, ENGLISH-SPANISH (GLOSARIO DE LA TERMINOLOGIA AUTOMOTRIZ. ESPANOL-INGLES, INGLES-ESPANOL)

The first section lists Spanish terms followed by their English counterparts; the second lists the English terms first. Both lists are arranged alphabetically. Indication is made of those English entries which translate Spanish verbs or phrases containing verbs, those containing language that applies only to Great Britain, and those with language applying only to the U.S. No attempt has been made in this edition to point out the substantial differences in automotive terminology which exist among the Spanish-speaking countries.

1978 NORTH DAKOTA VEHICULAR ACCIDENT FACTS

Statistical information is tabulated for 1978 vehicular accidents for all highway systems within North Dakota: driver characteristics, cost, fatalities, injuries, age and sex of those involved, violations/convictions, alcohol involvement, locale, vehicle type, environmental and road conditions, time of day and month, accident type, contributing factors, vehicle defects, and nontraffic accidents. A map of the state showing the fatality rate for each county is included. In 1978, there were 18,037 traffic accidents in the state (vs. 17,577 in 1977). There were 185 fatalities (vs. 180 in 1977) and 6206 persons injured (vs. 6346). Forty-two percent of the fatal accidents occurred after dusk and before dawn; 64% occurred on dry surface with clear weather conditions. Of the licensed drivers in North Dakota, 7.3% were involved in a traffic accident. The fatality rate (deaths per 100 million vehicle miles traveled) was 3.50, compared to the national rate of 3.27.

ADHESIVES FOR THE BONDING OF GRAPHITE GLASS COMPOSITES

An adhesive bonding study was conducted to generate data required for the full utilization of graphite and continuous glass reinforced plastics in lightweight vehicle production. A wide range of acrylic, epoxy, and urethane adhesives was screened on the basis of strength comparisons of adhesive-bonded samples at elevated temperatures and under different surface treatments, cure cycle, and bond thickness conditions. Three adhesives were selected for further evaluation: EA 934, epoxy; PG 6040/6045, urethane, and Li 59/260, acrylic. All three adhesives showed a small decrease in lap shear strength at bond thicknesses up to 1 mm. The acrylic and urethane adhesives showed maximum bond strength on a primed surface which had not been scuff-sanded. The epoxy adhesive, which required either scuff sanding or flame treatment to prepare the surface for good bonding, retained more than 90% of its room temperature properties at 93 degrees C; the other two adhesives had a 60% strength retention at this temperature. All three adhesives could be cured at room temperature. At room temperature and at 0.50 mm bond lines, all three adhesives produced bonded structures with Joint Stiffness Efficiency (ratio of measured flexural modulus of two 1-in wide laminates bonded together with the adhesive, to the flexural modulus of the base laminate) greater than 75%. In environmental studies, the lap shear strength of all three adhesives was minimally affected by soaking in distilled water at 82 degrees C for 14 days. The bond stiffness efficiency of the urethane joint dropped sharply, indicating substantial plasticization of the adhesive. The epoxy adhesive was the only one unaffected by aging 14 days at 149 degrees C.

MOTORISTS' UNDERSTANDING OF TRAFFIC CONTROL DEVICES

A research-test film and questionnaire were used to measure motorist understanding of certain traffic control devices (TCD's) in actual driving situations. Over 3000 drivers from across the U.S. participated in the program which tested the comprehensibility of 23 different scenes of 16 TCD's (signs, markings, and signals). Driver understanding of traffic controls was found to range from only 18% on one control to a high of 97% on another. No control device was understood by all drivers. Even the best understood signs were not well understood by 5% to 10% of the drivers. Drivers understood symbol signs better than either signals or pavement markings. The differences in the important symbols for SCHOOL ZONE and SCHOOL CROSSING were misunderstood by a significant proportion of drivers. The fairly recent nationwide usage of a solid, single, yellow pavement roadway marking has caused a high level of misunderstanding. Only three out of ten drivers understood that on a two-way, rural roadway, passing is allowed on the single, solid yellow line; most drivers thought the solid yellow line meant "no passing permitted". Another significant finding is that motorists do not fully understand and recognize the significance of "orange" background signs indicating highway construction zones. Older drivers (over 49) showed generally less accurate comprehension of the traffic controls; drivers aged 24-29 had the best understanding; younger drivers (under 24) had a slightly better comprehension than older drivers. There were no strong overall trends in comprehension differences between males and females.

COMPARISON OF MODEL CALCULATIONS AND EXPERIMENTAL MEASUREMENTS OF THE BULK CYLINDER FLOW PROCESSES IN A MOTORED PROCO (PROGRAMMED COMBUSTION) ENGINE

As an initial step in a systematic investigation of design parameters of the Ford PROCO (Programmed Combustion) engine affecting in-cylinder fluid motion, fuel/air mixing, combustion, and heat transfer, bulk cylinder flow as influenced by design and operating variables was studied in a PROCO Flow Simulation (PFSIM) model. The model was developed to calculate the angular velocity (swirl) and radial velocity (squish) as a function of crank angle for the four strokes of the motored engine cycle. The PFSIM model also calculates the time dependent cylinder pressure, temperature and mass, and accepts the following swirl-related parameters as input: dimensionless angular momentum and mass flow coefficients for a specific intake and exhaust system configuration. These parameters determine the intake-generated swirl which is computed from the angular momentum flux entering the cylinder during the induction process. An angular momentum flux swirl meter was used to obtain the required input data for three different intake port configurations, and calculations of the bulk cylinder flow were carried out with PFSIM for each intake port configuration. Experimental measurements of in-cylinder swirl were obtained with the spark discharge/time-of-flight method in a motored PROCO research engine for the same three intake ports. Good agreement was found between measured and calculated swirl velocities. The importance of angular momentum dissipation within the cylinder is indicated by the results of this investigation. In further model calculations, the sensitivity of swirl and squish to changes in piston geometry has been shown.

ROAD ACCIDENT INVOLVEMENT PER MILES TRAVELLED--PART 5

In a report on methods and results of the Queensland (Australia) Vehicle-Mile Performance Survey, the relationship of driver sex to accident involvement is analyzed, using statistical data on motor vehicle accidents in the state. One important finding is that, on the whole, women appear to be less accident involved, having less than 80% the involvement rate of men. However, a female is not necessarily a better driver. Considering the significant differences in the frequency distribution of the various types of vehicles used, trip types, and time and spatial variations and driving conditions, all of which place the male driver at a disadvantage, there is no uniform basis upon which a valid driving comparison between the sexes can be made. It was found, as expected, that there is a higher accident involvement rate (per miles traveled) among both male and female youth. The female involvement rate curve is, up to the age of 40, very similar to, and practically parallel with the male curve, but at a lower level. From age 40 on, it starts to rise; somewhere in the mid-forties it crosses the male curve and remains above it. No known earlier studies have observed this higher accident involvement for females of all age groups after 40, culminating in the 50-59 age group. Every subdivision of female drivers by any other variable was found to exhibit this trait. Other comparisons between male and female drivers concern accident severity, accident type, vehicle type, area of occurrence, day of week, hour of day, number of occupants, and car design characteristics. The age-specific involvement rates of the two sexes are compared with respect to factors including accident locale (metropolitan, provincial urban, or rural), and type and severity of accidents.

THE USE OF MULTIPLICATIVE MODELS FOR ANALYSIS OF ROAD SAFETY DATA

Accident ratios are analyzed with regard to two variables: road-surface skidding resistance and hourly traffic volume. In a first analysis, the Additive Conjoint Measurement model is used to investigate to what extent the accident ratios can be described as a result of independent contributions of skidding resistance and traffic volume. It is further considered whether these contributions have to be combined in an additive or multiplicative way. Based on the results of this investigation, a second analysis combines stochastic interpretation of the data with the multiplicative model. This Weighted Poisson model is a generalization of the log-linear model, recently proposed for the analysis of contingency tables. It is concluded that the multiplicative model describes the data better than the additive model, and that there is no interaction between skidding resistance and traffic volume in their effect on accident ratios. The relation between accident ratios and both variables are shown, and the statistics regarding the contributions of the variables are given.

INFORMATION CONCERNING DRUGS AND DRIVING RECEIVED BY CUSTOMERS OF PHARMACIES

An epidemiological questionnaire study was conducted concerning alcohol, drugs, and driving in Finland. Four issues were of interest: prevalence of persons holding a valid driver's license among customers of pharmacies; prevalence of drug utilization (drugs having the potential to impair driving skills); patterns of alcohol use; and relative number of accidents encountered by drivers purchasing drugs in pharmacies. Drivers were classified according to alcohol and drug use and living district. Pharmacists recorded prescription and over-the-counter drugs bought by their customers; 100 consecutive customers who bought oral prescription drugs in pharmacies were asked if they had a driver's license and whether their physician had told them about the effects of drugs on driving skills. Information was obtained by interviewing 984 customers concerning the possession of a driver's license, drug use, alcohol consumption, and whether their physician had told them about the mechanism of action and side effects of drugs. Results showed that about 60% of customers having a driver's license purchased drugs which may have deleterious effects on driving skills. Only 20% of these subjects had received information concerning drugs and driving from their physicians. In urban areas, alcohol and drug users had 1.5-2.5 times increased traffic accident involvement compared with nonusers. Nearly all pharmacy customers used drugs they bought by themselves. The need to inform the public about the effects of drugs on daily activities, road traffic accidents, and occupational hazards is emphasized.

ROLE OF PRIMARY PERSONALITY FACTORS IN THE PERCEPTION OF TRAFFIC SIGNS AND DRIVER VIOLATIONS AND ACCIDENTS

Relationships among personality dimensions, driver behavior, and performance in driving-related tasks were studied, and the need to evaluate these relationships in terms of primary personality dimensions was explored. Research indicates that greater field dependence, i.e., perception dominated by overall field organization, is associated with poorer performance in various driving-related tasks. Psychometric studies suggest the appropriateness of Eysenck's higher-order dimensions (extroversion, neuroticism, and psychoticism) in evaluating individual differences in driver behavior. The utility of using subscale scores reflecting the multidimensional nature of the extroversion scale rather than using overall extroversion scores has been demonstrated, as well as covariation between extroversion and field dependence. Reported relationships involving extroversion pertain to impulsivity, sensation-seeking behavior, fast decision time, and verbal and symbolic message types. In general, research implies that subscale scores reflecting primary personality dimensions should be used to assess driver behavior, particularly with respect to traffic sign perception.

CRASH INJURY PREDICTION MODEL

Automobile crash injury was analyzed using data from the Crash Performance Injury Report for crashes occurring since 1 Jan 1970 which involved 1969 or newer cars, vans, and pickup trucks. Two important injury prediction variables, functions of impact velocity and vehicle size, were incorporated in the crash injury prediction model. The model was developed using delta V (related to decelerations and forces imposed on vehicle occupants), vehicle weight, occupant age, seating position, crash configuration, and restraint usage to predict the expected abbreviated injury scale (AIS). The expected AIS was then employed to estimate the probability of death and severe injury. Model estimates approximated the observed probability of death and severe injury from the National Crash Severity Study data file. Analysis results emphasize the importance of crash severity measurements such as delta V. Supporting equations are provided and procedural information is appended.

HS-026 971

VEHICLE AGGRESSIVITY MEASUREMENT AND EVALUATION

Methods for evaluating vehicle aggressivity are presented, and a test methodology is introduced which offers the potential to standardize aggressivity and compatibility testing. Aggressivity refers to the characteristic of a vehicle structure that imparts a momentum change to another vehicle and penetrates that vehicle's structure during a crash event. The term also refers to the capability of a vehicle to coexist in a crash environment with a full spectrum of vehicles. Several methods are being investigated by the National Hwy. Traffic Safety Administration and others to measure and evaluate vehicle compatibility. These methods, successful in identifying factors that contribute to aggressivity, include the use of a honeycomb front impact barrier to measure loads across the vehicle frontal area. Analytical methods are available to model a combination of vehicles in frontal collisions and associated occupant responses. A theoretical model to measure aggressivity concentrates on the effective use of energy consumed in a crash event in order to maximize crash protection, minimize aggressivity, and achieve a high level of compatibility. The new methodology uses a deformable barrier in frontal impact testing, modeled to represent a nonaggressive vehicle. The barrier is used as a standard against which aggressivity characteristics of all cars can be measured.

DEVELOPMENT AND USE OF A CYCLE SIMULATION TO PREDICT SI (SPARK IGNITION) ENGINE EFFICIENCY AND NOX (NITRIC OXIDE) EMISSIONS

Computer simulation of the four-stroke spark ignition engine was developed to study the effect of variations in engine design and operating parameters on engine performance, efficiency, and nitric oxide (NO) emissions. The simulation computes flows into and out of the engine; calculates changes in thermodynamic properties and composition of burned and unburned gas mixtures within the cylinder through the engine due to work, heat, and mass transfers; and follows the kinetics of NO formation and decomposition in burned gas. The combustion process is specified as an input to the simulation program through the use of a normalized rate of mass burning profile. From this information, the simulation computes engine power, fuel consumption, and NO emissions. Predictions made with the simulation are compared with data from a single-cylinder Cooperative Fuels Research engine over a range of equivalence ratios, spark timings, and compression ratios. Predicted fuel consumption and NO emissions show acceptable quantitative agreement with the data. A parametric study of variations in load, speed, combustion duration, timing, equivalence ratio, exhaust gas recycle, and compression ratio is reported. Parameters selected for the study using a 5.7-liter displacement engine included variations in brake-specific fuel consumption, brake-specific NO emissions, and mean exhaust temperature. Supporting data and equations are appended for thermodynamic properties, energy conservation, and NO kinetics.

COMFORT CRITERIA FOR AIR CONDITIONED AUTOMOTIVE VEHICLES

Human response to the thermal environment in air-conditioned automobiles was explored, with emphasis on comfort criteria. In one study, 2,200 subjects were exposed for 45 minutes to an environment of 110 degrees F/40% relative humidity in a 1973 Ford vehicle to evaluate effects of register size, air flow rate, and discharge air temperature on comfort. The time to reach a comfortable condition was not affected by register size, but it varied in the front seat from four minutes (air flow of 400 cubic feet per minute (cfm)) to 18 minutes (150 cfm). In the rear seat, corresponding times were 8.5 and 39 minutes. In another study designed to define criteria for comfort during a prolonged stabilized period after transient cool-down, a 20-mph 30-minute cool-down followed by a 60-minute 40-mph steady-state condition was simulated with a chamber environment of 110 degrees F/ 40% relative humidity and 90 degrees F/70% relative humidity. The average time to reach comfort was reduced by 55% when temperature was reduced from 110 to 90 degrees. At 90 degrees, blower speed was changed three times more frequently, the register vane setting was changed the same number of times in both studies, and the average time before front seat passengers deflected register plumes off themselves was the same in both conditions. Another study determined comfort response to seasonal acclimation. Subjects tested in the winter exhibited a thermal sensation response higher than that of subjects tested in the summer; the time required for winter subjects to reach comfort was longer than for summer subjects.

HEATING AND AIR CONDITIONING A HEAVY TRUCK

The design of a climate control system for new highway tractors is described. Engineering is accomplished in three phases: establishing objectives; designing the system; and testing to confirm that objectives are met. General vehicle and specific system requirements were established for a Ford tractor. System design considered operator comfort, zone control, packaging, case design, heater cores, the evaporator core, the condenser core, and control actuation. A multiple heater-evaporator system emerged with performance superior to existing designs. The system has three sets of controls which regulate temperature in driver, passenger, and sleeping areas of the tractor cab. Packaging concepts, selection of the power medium for controls, and system testing are discussed.

SOME DESIGN CONSIDERATIONS OF AUTOMOTIVE GAS TURBINES

Design and manufacturing aspects of gas turbine automobile engines are addressed. Gains in cycle thermal efficiency with increasing peak temperatures are examined in view of performance penalties due to engine size effects. Thermal efficiency was investigated using a 75-hp and a 150-hp gas turbine. Attention was paid to current and advanced design and manufacturing technology related to rotor clearances and blade thicknesses. Design and manufacturing limits used to define engine penalties with advanced technology were qualified. Results indicated an improvement of about 15% in thermal efficiency due to increasing the peak cycle temperature from 1850-2500 degrees F for a gas turbine engine suitable for an automobile but requiring advanced technology. Size effects between 75 hp and 150 hp only resulted in about a 2% penalty. With current design and manufacturing technology, the increase in thermal efficiency declines from 15% to 10%, assuming that ceramics can be utilized to achieve a 2500-degree F turbine inlet temperature. Without a ceramic turbine rotor and with cycle temperature limited by the capability of some type of metallic rotor, the gain in thermal efficiency further decreases to about 5%.

FIELD EXPERIENCE WITH THE DETROIT DIESEL ALLISON 404/505 INDUSTRIAL GAS TURBINE ENGINES

The Detroit Diesel Allison Div. of General Motors conducted a field evaluation program from 1974-1977 on the 300-hp GT-404-3 and the 390-hp GT-505-3 industrial gas turbine engines. The overall program plan involved installations in trucks, coaches, and marine and industrial environments. Emphasis was placed on operator reaction, environmental effects, performance, and field-revealed problems. Two particular applications were explored in detail: bulk hauling trucks with self-unloading capabilities, and Greyhound intercity coach operation with gas turbine power and automatic transmissions. The gas turbine engines performed well in all applications. Operators liked the engines, particularly the smoothness, quietness, and excellent torque characteristics. The performance of heavy trucks and coaches on ice was superior, both during engine braking and starting on hills. Brake life on trucks and coaches was extended by about 50%. Trip time was generally better than with equally powered diesel vehicles. Fuel consumption of the engines was not competitive with comparable diesel engines, being about 15-20% poorer in typical applications, and durability and reliability needed improvement.

MECHANIZED UTILITY TRUCKS--A COMPLETE PACKAGE

Factors are discussed for selecting the right utility truck and mounting mechanized equipment (e.g. digger-derricks, aerial lifts) to the truck chassis. The installation of mechanized equipment is costly and time-consuming. Utility derricks are normally offered in three different mounting types (right corner mount, centered over rear, and centered behind cab), and utility lifts in two different mounting types (rear mount lift and behind the cab mount lift). Stability, winch options, aerial basket trucks, the truck cab, and four-wheel drive must be evaluated in mechanized equipment selection. The key guide in selection is to get the job done efficiently at minimum cost; this can only be accomplished if the person writing the specifications is thoroughly familiar with the user's requirements or unusual working conditions, as well as with maintenance requirements and operating limitations of the equipment.

LIFE TESTING OF LEAD ACID BATTERIES FOR ELECTRIC VEHICLE DUTIES

The Lucas electric vehicle battery was developed on the basis of the multiplate multicell automotive battery with its polypropylene case and associated technology, by improving its life cycle capability without losing energy density and departing significantly from standard production methods. The Lucas program consisted of four elements: unit battery cycling (preliminary screening); pack cycling (first stage proving); accelerated in-vehicle testing (second stage proving); and monitored operator usage (third stage proving). The choice of a lead-acid battery for development was made as a result of extensive studies dealing with potential electric vehicle battery systems and transport needs. Key battery requirements defined for testing were an energy density of at least 18 Wh/lb, discharge at about a 2-hour rate in order to meet speed, acceleration and range criteria, and a minimum life cycle in excess of 500 cycles. Testing involved unit battery cycling, laboratory pack cycling, and accelerated in-vehicle operation. Much of the experience gained is applicable to any electrochemical couple being developed for electric vehicle use.

ELECTRIC VEHICLE BATTERY DEVELOPMENT

An electric vehicle battery is being developed that uses expanded metal, nonantimonial alloy grids, enveloped separation/retention, and high-rate production methods of packaging, including through-the-wall construction. The battery is expected to meet Department of Energy goals for the improved state-of-the-art electric vehicle battery and to be further improved to meet department goals for the advanced battery. Capabilities of electric vehicle batteries (existing and under development) are discussed. The design of improved batteries is addressed and design tradeoff studies regarding active materials, separators, electrolytes, and packaging are reported.

240 VDC (VOLT DIRECT-CURRENT) ELECTRIC VEHICLE SYSTEM

Effects of system variations on battery performance, as expressed by electric vehicle range, were investigated. Electric vehicle performance efficiency is a function of total system efficiency and compatibility. Work with a 240-volt electric vehicle battery power system assumed that higher voltage would yield better efficiency through reduced system resistance and lower current spikes as compared to 120 volts or less. The actual range of the 240-volt battery configuration was approximately 25% less than the 120-volt system. The loss was caused primarily by incompatibility between the motor and chopper control in the higher voltage battery application. Extremely high current spikes resulted from this incompatibility, thus providing the required current in a very inefficient form. High-voltage electric vehicle power systems can provide performance advantages over lower voltage systems only if voltage balances with the total system. Mixing high-efficiency components does not assure total system efficiency optimization. The ability of a battery to release its stored energy is a function of the demand upon it. Higher current demand will reduce battery efficiency.

CALIFORNIA DEPARTMENT OF MOTOR VEHICLES RESEARCH STUDIES. A SUMMARY OF FINDINGS AND ACTIVITIES

A bibliography is presented of summaries of research study findings and activities conducted by the Res. and Devel. Section of the Calif. Dept. of Motor Vehicles. The following information is given for each item: title, author(s), funding source, date, report number(s), objective, abstract, implementation of findings and recommendations, and supplemental information. The material is organized under the following headings: driver education and training effectiveness studies; driver licensing screening effectiveness studies; effectiveness studies on improvement and control of deviant drivers; basic research and methodological studies: driver performance, accident etiology, prediction models, and research methods; driver licensing/control systems and safety management studies; studies on special driver populations; and miscellaneous studies and reports. Studies in process are usually listed at the end of each section, and cross references are provided to related studies. An author index, a list of journal publications, a list of available publications by report number, and National Technical Information Service price codes for North America are provided.

A COMPARATIVE ANALYSIS OF TRUCK ACCIDENTS IN THE STATE OF MICHIGAN

A two-stage analysis of accident and travel data (Sep 1978-Mar 1979) was conducted, comparing Michigan truck accident experience with that of other motor vehicles (nontrucks). Accident data were compared according to three severity schemes (fatal, personal injury, and property damage) for trucks and nontrucks. Truck accident data were further classified in terms of pickups/panels/vans (PPV's), straight trucks, and truck tractors. A separate comparison of accident data was made between each truck category and all other nontrucks, and accident data for the three truck categories were also compared among themselves. Annual accident rates were computed from historical accident and exposure data, and compared using appropriate statistical methods. Rates were derived by dividing the number of accidents by corresponding exposure data, as indicated by the number of vehicle miles traveled. For fatal and property damage accidents, trucks had a higher rate than nontrucks. For injury accidents, trucks had a lower rate. For all accidents considered together, there were no significant differences between accident rates. In almost all accident categories, PPV's and straight trucks had a higher accident rate than nontrucks, while truck tractors had a higher rate for fatal accidents only. In all other severity categories, truck tractors had a lower rate than nontrucks. Straight trucks had the highest accident record overall, followed by PPV's and truck tractors. Truck tractors had a higher fatal accident rate than PPV's. Recommendations for future studies are included.

LESSORS URGE FLEETS TO SHIFT TO SMALLER CARS

Automobile leasing company use of small fuel-efficient cars is considered in light of gasoline prices and low availability. The 1980 Gelco Guide organizes 1980 models in five basic selector groups, each targeted to a specific corporate functional area. The "position image" group includes vehicles priced between $6,700 and $8,200, having an average fuel rating of 16 mpg. The "economy" group is comprised of vehicles priced from $4,900 to $5,200, having an average fuel rating of 21 mpg. The mid-size "functional image" group is rated as the one with the best overall value. Selection of the best cars to lease depends on fuel prices, future availability of fuel, and effect of fuel factors on used car prices. One leasing corporation recommends that fleets use mid-size vehicles regardless of the number of miles driven per year and use a large vehicle (115-inch wheel base) only when necessary. Another company suggests upgraded models with more luxurious accessories instead of large vehicles if image is important. Six-cylinder engines are preferred in terms of fuel economy, performance, and durability. Replacement cycles for leased cars are discussed, and specific car models and manufacturers are evaluated. In a separate section, the Free-Way 3-wheeled, one passenger car is described. Built by H-M Vehicles, Inc., of Bloomington, Minn., the vehicle has a fuel economy of 100 mpg with a top speed of 65 mph; the electric version has top speed of 55 mph and can go 40 miles on a single charge. The diesel version's fuel consumption is 140 mpg with a top speed of 60 mph.

ANALYSIS OF FATAL ACCIDENT TRENDS ON MARYLAND HIGHWAYS, 1970-1976

Although Maryland's imposition of the 89 km/h (55 mph) speed limit has been credited with the reduction in traffic fatalities, the magnitude of its effect as a "lifesaver" may be less than was previously assumed. A review of previous research reveals that in-depth statistical analysis was not employed. New research was begun in late 1975 to statistically analyze fatal accident data between 1970 and 1976, using various multivariate regression analysis techniques. Four of the fifteen variables studied--the normal historical decline in fatal accident rates with time, changes in the posted speed limit, changes in the level of traffic volume, and increases in police enforcement--statistically contribute to the explanation of the raw variance in the number and rate of fatal accidents. These four variables account for more than two-thirds of the total variance. Techniques for analyzing data from these highly intercorrelated variables are discussed and employed. Additional research is required in other parts of the United States to confirm or deny the results obtained in Maryland.

RAISED PAVEMENT MARKERS FOR CONSTRUCTION ZONE DELINEATION

In 1976, the Implementation Division of the Federal Hwy. Administration initiated a series of projects to evaluate the effectiveness of raised pavement markers for guiding traffic through construction zones. During the 1976 and 1977 construction seasons, nine state highway agencies installed several types of reflectorized raised pavement markers on construction projects, including bridge construction, interchange reconstruction, and roadway widening. The cost, spacing, and ease of application and removal of the markers, and their effectiveness as traffic guides during the day and at night were evaluated, as well as the public's acceptance of the markers. The general conclusion of the participating state highway agencies was that raised reflective markers provide excellent nighttime temporary delineation, particularly when the road is wet, at a low cost and with little or no maintenance. On two projects, the use of the raised pavement markers resulted in a reduction of accidents. Comments from construction personnel and the public on the effectiveness of the markers were favorable.

PREDICTION OF HIGHWAY TRAFFIC NOISE

The Federal Hwy. Administration has developed and calibrated a model for predicting vehicular noise from highways, based on a method of physically significant adjustments. Use of the model is straightforward and requires minimal training. The model's flexible design allows the more advanced users to modify it to meet specific site requirements. Five levels of sophistication have been developed to extend the model's usefulness: a nomograph, a manual method, a hand-held calculator, SNAP 1.0 (Level 1 computer program), and STAMINA 1.0 (Level 2 computer program).

TAKING THE MESSAGE TO WASHINGTON: R AND T (ROAD AND TRACK) GIVES A CONGRESSIONAL BRIEFING ON AIRBAGS AND OUR READER SURVEY

A summary is presented of Road and Track's 1979 congressional briefing and technical presentation on the subject of airbags, made at the invitation of Congressman John D. Dingell (D-Mich), one of eighteen sponsors of an amendment to a Dept. of Transportation appropriation bill that would restrict airbag funding to research and development. Road and Track staff presented data indicating the ineffectiveness of airbags in side crashes and rollover accidents and raised questions regarding airbag cost, effectiveness, reliability, and disposal. Pro-airbag representatives, including Ralph Nader and officers of corporations currently involved in airbag manufacturing, presented contrasting views. Each group claimed that "factual errors" were made by the other.

FUEL FOR THOUGHT

A brief summary is provided of the American automaking industry's response to government mandates to "reinvent the automobile" to achieve increased fuel economy. The high cost of meeting government regulations is noted ($1.6 billion for General Motors in 1978). General Motors anticipates a per car cost increase of $390 to reach 1985 fuel economy levels of 27.5 mpg. The need for the prompt development of alternative energy sources is discussed. The possible introduction of new model lines by U.S. and Japanese manufacturers is mentioned, and the present and possible future dissolution of ties between U.S. and Japanese auto manufacturers is briefly discussed.

URBAN TRANSPORTATION PLANNING FOR GOODS AND SERVICES: A REFERENCE GUIDE

A reference guide is provided to address short-range traffic engineering and transportation planning needs associated with the urban trucking process, which is described and discussed in terms of traffic volume, types of vehicles, and truck trip characteristics. The scope of the urban trucking process encompasses terminal activities, stem driving (between terminal and pickup/delivery zone), intrazone driving, and stop or dwell time; types of trucks are considered (mostly light trucks with 2 axles and 4 tires), constituting about 15% of urban traffic, with traffic variations according to hour, day and month. Truck trip characteristics affecting traffic include trip purpose, urban truck parking, and truck operations. The need for analyzing energy, environmental, and urban planning factors related to truck use is identified. Approaches are presented for forecasting truck travel, conducting truck short-counts, and estimating truck loading space demand. Guidelines are presented for identifying, implementing, and assessing traffic improvements. Selected improvements to general traffic flow are discussed, including physical system improvements, one-way streets and reversible lanes, improved traffic signal systems, intersection improvements, and peak-period parking prohibitions. Selected short-range truck-oriented improvements include allocation of curb space, operational/physical constraints to trucks (turning radii, weight limits), and restricted roadways. Long-range truck-oriented improvements include designated truck routes and ramps, development of off-street and underground truck loading facilities, and use of consolidation terminals.

SPEED ADVISORY INFORMATION FOR REDUCED VISIBILITY CONDITIONS. EXECUTIVE SUMMARY. FINAL REPORT

Preliminary design specifications were developed for a speed advisory system for use during periods of reduced visibility (fog). Necessary facilities, equipment and procedures to conduct controlled experimentation under various levels of fog density were developed. A series of interrelated experiments were performed to identify optimum advisory information (sign messages and speed values), and the number, locations, and interconnections between signs which would result in the smoothest traffic flow. This information, as well as the pertinent literature, was utilized to develop preliminary specifications for a full-scale advisory system for use on the public highway. Results indicate that a single speed advisory sign prior to a fog zone will result in earlier and more gradual driver deceleration and reduced traffic flow instability. Data analysis indicates optimum posted speeds for each set of visibility conditions. Raised reflective centerline and/or edgeline buttons did not significantly increase traffic flow stability, although 91% of the subject drivers regarded them as an aid in keeping on the road in light and moderate fog. Sign-by-sign analysis indicated that the use of speed differentials and active (flashing) signing yielded lower speeds and smoother deceleration profiles.

THE FARS DATA AND SIDE-IMPACT COLLISIONS (FATAL ACCIDENT REPORTING SYSTEM)

Information on side impact fatal accident cases was extracted from the National Hwy. Traffic Safety Administration's 1977 Fatal Accident Reporting System (FARS) files, combined with parallel information from the National Crash Severity Study (NCSS), and used to estimate the relative frequency of various kinds of side impact collisions. The analysis, restricted to passenger cars, estimated the number of fatalities, the total number of occupants in all towaway crashes, and the ratio of these two numbers. Data are shown for right and left side impacts, for vehicles impacted by other cars, by trucks, or by fixed objects, and for drivers vs. other seating positions. About 60% of the side-impact fatalities in passenger cars in the U.S. occur as the result of the car being struck by a truck or striking a fixed object; most of the other 40% result from impact by another passenger car. This analysis was undertaken to assess the value of the FARS data in providing an understanding of a particular accident type. The conclusion is drawn that FARS is useful now, and is likely to be more so in the future. Since it contains the census of fatal highway accidents in the U.S., conclusions drawn from this file are limited only by inaccuracies in the data and not by statistical sampling considerations.

THE MOPED REPORT

A "state of the art" study was conducted on the moped in Ohio and other states to assess its impact upon traffic safety and to provide suggestions for future action. A brief history of the moped in Europe and the U.S. is presented, as are findings on the impact of moped market growth and a history of Ohio legislation governing mopeds. Although a general lack of moped accident data is recognized, five studies sponsored by the National Hwy. Traffic Safety Administration are briefly described. Tabular data are presented on moped legislation in 36 states and the District of Colombia and on moped operating specifications (maximum speed, brake horsepower, engine displacement, operator age, and operation requirements). Moped popularity is attributed to its mechanical simplicity, economy, and environmental desirability. Major factors affecting moped safety are the youth and inexperience of many riders; improper braking and signalling; lack of protective clothing and headgear; overloading (with passengers or parcels); lack of power; poor visibility; and vehicular instability. Recommendations developed by the Ohio Board of Education call for increased research and improved Federal standards (specifically Federal Motor Vehicle Safety Standards 108 and 123) and legislation which defines the moped and mandates safety rules, age limits for ridership, and testing/licensing/registration procedures. Other recommendations are for structural modifications to mopeds and automobiles to reduce collision-related injuries, and for improved consumer/rider education programs. Appended are Federal Motor Vehicle Safety Standards relating to the moped, Ohio rules for motorized bicycle equipment and qualifications, current moped legislation in Canada (tabulated), a course outline for moped safety, and a bibliography on mopeds.

TRANSPORTATION AND ENERGY. URBAN TRANSPORTATION DIVISION SPECIALTY CONFERENCE PROCEEDINGS, WASHINGTON, D.C., MAY 22-24, 1978

Over 25 papers and panel sessions are reported from a conference designed to provide an opportunity for decision-makers, engineers, and planners to update their skills and understanding of transportation and energy issues. Five papers covering energy efficiency, energy transportation studies, and transportation energy conservation were presented at two general sessions. Sixteen papers are reviewed from six work sessions on the following topics: environmental effects of conservation, social and economic effects of conservation, modal energy efficiencies, practice in traffic operations and engineering, practice in regional transportation and land use approaches, and practice in institutional analysis. Four other papers are reviewed from an evening short course on ethics for a people-serving profession. Also included are five papers submitted for publication which cover transportation efficiencies and vehicle occupancy rates, intercity freight energy policy analysis, a transportation energy conservation case study (Pennsylvania), a technique for assessing the fuel conservation program of a ground transportation system, and coal haul road research and mapping.

SYNTHESIS (OF THE CONFERENCE ON TRANSPORTATION AND PLANNING)

In a summary of the conference on transportation and planning, Dr. Bellomo outlines the major policy issues: need for improved institutional arrangements and regulatory reform; significance of short-term transportation energy conservation measures; lessons to be learned from development of Transportation Control Plans by the Environmental Protection Agency; how to deal with the revenue shortfall due to lower fuel consumption and higher highway construction and maintenance costs; and balancing supply and demand for energy. The issues are discussed from the Federal, Congressional, state, local, and private perspectives. A discussion of issues and opportunities in the practice of planning and engineering includes institutional concerns, modal efficiency, traffic operation and engineering, regional transportation/land use planning, and impact assessment. It was concluded that there is need for leadership by the civil engineering profession.

TRANSPORTATION CONSERVATION: CAN WE DELIVER?

The worsening balance of payments suffered by the U.S. as a result of increased oil imports is described, as is the less than expected fuel economy of vehicles. The highway vehicle is seen as the largest single consumer of energy. Elements of the National Energy Plan are outlined: taxes for fuel-inefficient cars, tax credits for home insulation, encouragement of coal conversion, natural gas deregulation, utility rate reform, and the crude oil equalization tax. Proposals are made for state and local initiatives in conserving transportation fuels: promote more efficient transportation modes (i.e. carpools, enforcement of 55 mph speed limit, priority to high-occupancy vehicles), improve vehicle efficiency (by graduated registration fees, elimination of unnecessary traffic controls, efficient vehicles for state fleets), and discourage use of private automobiles (parking control, zoning regulations). Conservation options under development for the future are described: promotion of improved vehicle management practices (procurement, maintenance, operation), promotion of ride-sharing and vanpools, electric vehicles, synthetic fuel (gasohol), and new engines (Stirling, gas turbine). The conference's emphasis on near-term conservation options is applauded, since transportation will bear the brunt of any future fuel crisis, and agreement is urged on decisions that will lead to prompt action.

ENERGY EFFICIENCY: WHICH MODES, WHICH PROGRAMS?

The analysis presents several measures of energy use, from propulsion needs to program energy savings. Under consideration are the energy needs for building roadways and tracks, for manufacturing and maintaining vehicles, for heating and lighting stations, and for driving to stations. Also considered are the directness of alternative modes of travel, and the energy implicit in travel patterns prior to changes in public transportation policy. These energy components of urban transportation are combined to form an hierarchy of four measures of energy use, including means of computation: energy intensiveness, line-haul energy, modal energy, and program energy. Using these measures, the following alternative transportation modes are compared: carpool, vanpool, dial-a-ride, heavy rail transit (new), commuter rail, light rail transit, and express bus service (new). Of these, carpooling and vanpooling offer the greatest potential for fuel conservation per passenger mile. Express and other innovative bus services promise substantial savings per passenger mile and offer greater opportunity for Federal promotion efforts. Since heavy rail relies on automobile access and draws from other energy-efficient modes, it does not appear to be a good basis for a fuel conservation program. Dial-a-ride is found to be the least fuel-efficient alternative, although it has social advantages for transporting the elderly and handicapped.

ENERGY TRANSPORTATION STUDIES AND RELATED ISSUES

The National Energy Transportation Policy Study, planned by the Departments of Transportation and Energy, is discussed, as well as the results of recently completed transportation energy studies and various administration positions on transportation issues. Among the issues to be addressed by the planned study are the adequacy of railroad rates; environmental problems of increased coal transportation; financing the upgrading of roads in areas of coal mining operations; evaluation of the pipeline system; transportation of oil and gas; the need for new pipelines; and environmental and financial problems of unit train traffic, high-voltage electrical power transmission, and nuclear waste transportation. Topics of other studies include coal slurry pipelines, transportation of Alaskan crude, and liquified natural gas transportation.

TRANSPORTATION ENERGY CONSERVATION IN COLORADO

The role of transportation fuels in energy demand is addressed, especially in Colorado where the economic activities (agriculture and tourism) are energy intensive. The efforts of the Colorado Dept. of Highways in reducing transportation energy consumption are outlined. The 1977 Colorado State Energy Conservation Plan (SECP) is described, which projects an 8% reduction in energy consumption in 1980. Transportation measures in the SECP include the state bikeway program, urban area carpooling, vanpool demonstration program, public transportation improvements (exclusive bus lane, exclusive transit right-of-way, park-n-ride lots, high-occupancy vehicle lanes), purchasing of energy-efficient vehicles and equipment, 55 mph enforcement, and staggered work hours. Other state programs include asphalt recycling, evaluation of solar and geothermal energy, and natural ventilation of the Eisenhower Tunnel which presently costs $40,000/month for electricity. Long-term changes are envisioned in land use and metropolitan planning. Energy conservation impacts on highway finances are outlined, as well as problems of energy production which include providing highway facilities for greatly increased coal movement and its impact on highway/railroad crossings.

TRANSPORTATION PLANNING FOR AIR QUALITY IMPROVEMENT

The relation between air pollution control and urban transportation is discussed, with particular emphasis on factors affecting transportation planning. Of two basic issues, the first concerns the relation between transportation measures that improve air quality and those designed for other purposes; the second issue concerns the structure of urban transportation planning and decision-making for integrating air quality considerations into all phases (planning, decision-making, and implementation). The role of transportation planning and system management in air pollution control involves vehicle emission controls of carbon monoxide, hydrocarbons and nitrogen oxides, and implementation plans for local ambient air pollution control by improving traffic flow conditions and reducing traffic volume. Transportation measures that address specific air quality needs are identified as traffic engineering measures to improve traffic flow, transit improvement, and other measures to encourage use of high-occupancy vehicles and to discourage use of low-occupancy vehicles. Specific measures include auto-free zones, charging vehicles for entry into the central business district, improved transit service, and reduced transit fares. Provisions for integrating air quality considerations into transportation planning and decision-making are included in the Clean Air Act Amendments of 1977. The provisions require local coordination of transportation and clean air planning and encourage participation by elected officials and the public.

TRAVELERS' ATTITUDES AND ENERGY CONSERVATION

The factors which tend to affect travel behavior are discussed from three viewpoints: exogenous influencing factors (price and availability of fuel, price of automobile, transit availability, and level of service), household influencing factors (income, stage of life cycle, auto ownership, fuel efficiency of vehicle, and trip purpose and length), and individual influencing factors (education, income, stage of life cycle, sex, and location of residence or work place). The evidence of these influencing factors is described from opinion surveys regarding the 1973-1974 oil embargo, and related attitudinal and situational surveys. Results of a 1977 survey designed to identify attitudes and perceptions toward transportation problems and toward public and private transportation options indicate that Americans recognize that changes are taking place in their way of life and that they expect to make sacrifices. The American people tend to favor policies that increase transportation options and to oppose policies that limit options. Promising initiatives are: improving gas mileage in cars, improving and expanding public transportation, and encouraging carpooling. The automobile is valued for its speed and flexibility, and carpooling is expected to increase. Younger adults seem especially aware of transportation issues and problems. Consumer values related to new automobile purchases tend to stress interior size, with comfort and fuel efficiency following closely. There is increased interest in vans and trucks among certain groups.

TRANSPORTATION ENERGY CONSERVATION IN NEW YORK STATE

An assessment of energy conservation technologies in New York State transportation was broadened to include the form of transportation demand, programs, and policies. Energy savings were considered by three basic mechanisms: conservation, efficiency, and substitution. Three areas recommended for attention include motor vehicle transportation, transportation demand and planning, and public transportation. Among the topics discussed are transportation energy use, motor vehicle efficiency, transportation policies and programs, and public transportation (rail, bus, and paratransit). Opportunities for energy conservation cited as future possibilities include alcohol gasoline blends (raw materials available in New York), electric and hybrid vehicles, and diesel and other engines.

LIGHT VEHICLE TECHNOLOGY SUBSITUTION

Based on a broad definition of new technology and a premise that light vehicles will continue to be the principal means of transportation, the determinants of new technology substitution are examined. The crucial agent compelling technology substitution is exhaustion of petroleum resources. Policies designed to reduce the use of automobiles are politically unfeasible. It is stated that synfuels (from biomass, coal, shale, and tar sands) and electric vehicles (EV'S) are the only significant technology presently available. Cost is the principal deterrent to synfuels, as well as the lack of an existing infrastructure for large-scale production and distribution; vehicle technology will not need to be changed drastically. Conversely, the infrastructure exists for fueling EV'S; the problem lies in improving vehicle batteries. Critical barriers to the introduction of new vehicle systems technologies are discussed: Federal energy policy, which is based on continued use of petroleum fuels, and lack in the U.S. of cooperation between the public and private sector such as exists in Europe and Japan. Timing of the decision to convert either to synfuels or to EV'S is crucial to an orderly transition away from exhaustible petroleum resources.

ENERGY CONSERVATION IN URBAN TRANSPORTATION

In the light of the high oil consumption by transportation (97% of transportation energy is from oil; transportation uses 55% of all oil used in the U.S.), the possible approaches to energy conservation in urban transportation are reviewed in four categories: reduction of miles traveled; increase in passenger miles per vehicle mile; increase in vehicle miles per gallon or kilowatt-hour; and substitution of other energy sources for petroleum. Activities of the Urban Mass Transportation Administration (UMTA) are outlined under each category. To reduce miles traveled, low-occupancy vehicle travel is discouraged by exclusive bus lanes, auto-free zones, and parking restrictions; high-density land use is encouraged. To increase passenger miles/vehicle mile, conversion from automobile to transit, carpool, or vanpool is being demonstrated by UMTA in Knoxville, Norfolk, Minneapolis, and Marin Co., Calif. Reduction of energy consumption per vehicle mile is accomplished by increased efficiency in engines, drivelines, and accessories; reduced weight, rolling friction, and aerodynamic drag; use of braking energy; and replacement of under-utilized buses by paratransit. Examples are UMTA'S diesel taxi project, and installation of a flywheel in railcars and in diesel and trolley buses to store braking energy. Substitution of petroleum by other fuels (methanol, propane, hydrogen) and by use of electricity in rail systems, trolley buses, and hybrid buses is being explored.

TRANSPORTATION ENERGY CONSERVATION: INSTITUTIONAL CONSIDERATIONS

Some similarities and differences are outlined between earlier efforts to improve air quality through transportation controls and the current effort to conserve transportation energy. In both efforts, the decision-making processes were opened to state, metropolitan, and/or local agencies which had previously been only marginally involved. The differences lie in internalized benefits (consumers derive a greater direct benefit from energy conservation), geographical scale (air pollution was more localized), and time horizons (public appreciation of the energy crisis disappeared after the end of the Arab embargo). The lessons to be learned from air quality controls include those of conflicting objectives (trade-offs), intergovernmental and interagency relations (need for cooperation), metropolitan scale (appropriate area for making transportation trade-offs), attitudinal and behavioral constraints (problems of instilling a conservation ethic in the public), legal and regulatory constraints, and resource allocations. It is recommended that governmental agencies devise adaptive and flexible ways to reevaluate policies, programs and institutions to respond to changing values, goals, and conditions.

ENERGY AND EMISSIONS: THE SIMULATION APPROACH

Recent applications of computer simulation techniques by the Federal Hwy. Administration (FHWA) are described for the determination of energy consumption and vehicle emission characteristics in urban traffic and the effects of traffic control on energy consumption and emissions. UTCS-1, an FHWA surface street simulation model, was modified to estimate fuel consumption and emissions and was renamed NETSIM; another FHWA detailed freeway model, INTRAS, can also estimate fuel consumption and vehicle emissions. Experimentation with these models indicated that facilitation of vehicle movement usually directly improves fuel efficiency and vehicle emissions. Measures which improve average speed of vehicles in networks (i.e. one-way streets, pre-timed signals, right-turn-on-red) also proportionately improve fuel efficiency and emissions at least in cases where change in overall speed is due to changes in average number of stops and traffic interference. A traffic change which increases vehicle miles may result in a net increase in fuel consumption and vehicle emissions. It was also shown that pollution concentrations are much greater at intersections than at midblock; that pedestrian scramble systems (allowing pedestrian crossing in all directions at one signal phase) generally degrade speed, fuel consumption, and vehicle emissions; and that increased traffic density degrades traffic performance of a network, and increases fuel consumption and emissions.

DETERMINATION OF FUEL CONSUMPTION AND EMISSIONS

A methodology is described for providing up-to-date relationships among fuel consumption, emissions, vehicle operation, and highway design. A computerized fuel consumption and emissions model is designed to enable the designer or analyst to determine the fuel consumption and emissions that would result under any given conditions. The primary input categories for the model are roadway design parameters (grade, curvature, superelevation, pavement type, and length of section under analysis) and traffic flow characteristics (speed profile, vehicle mix, and traffic volume); a secondary input is provided for environmental conditions (precipitation, wind, and ambient temperature and pressure). Two principal submodels are the torque-roadway design correlation model and the fuel consumption/emissions rate model. The basic data for the submodels require a set of road tests to establish the relationships among energy (driveshaft torque), vehicle speed, and road geometry, and a set of dynamometer tests to establish the relationship among driveshaft torque, vehicle speed, and resulting fuel consumption and emissions. Tests will be made on a limited cross section of vehicle types (compact, subcompact, and intermediate cars, and four weight classes (2500-5500 lb) of trucks). By using the model, impact on energy and pollution can be assessed when a change is contemplated in roadway design, in the speed profile of a traffic stream, or in the composition of the vehicle mix. The basic data cells can be updated through a dynamometer test program whenever significant changes in vehicle fuel consumption and emissions occur. Applications of this project include determining fuel tax structures and rates, and justification and formulation of traffic management and air quality improvement programs.

ENERGY CONSERVATION AND TRAFFIC CONTROL AT LOW VOLUME INTERSECTIONS

An analysis is presented of gasoline consumption and air pollution resulting from stop, yield, and no sign controlled intersections under various traffic volume conditions. The data were obtained through the use of Federal Hwy. Administration and Environmental Protection Agency computer programs, modified to simulate traffic flow and energy consumption analysis, respectively. Regional estimates indicated a potential saving of several million gallons of fuel per year in Indiana alone, depending on the low-volume intersection signing policy adopted by municipal, county, and state authorities. A procedure is discussed to guide transportation engineers to an areawide optimal signing policy. More selective implementation of the proper type of control for unsignalized low-volume intersections can result in elimination of substantial waste in fuel without any technological breakthrough, without any financial investment, and without a long development delay. Improved vehicle emissions in suburban and urban locations are a side benefit of the program.

ENERGY IMPACTS ON PASSENGER TRANSPORTATION

Three national energy scenarios are outlined for 1990, with their impacts on the Tri-State Region (parts of New York, New Jersey, and Connecticut). The Tri-State Region received 13.1% of the nation's imported oil and 5.3% of its domestic production in 1975, a total of 1.33 MBD (million barrels of oil/day). This level would rise to 1.67 MBD under the "high" scenario, 1.45 MBD under the "NEP" (National Energy Plan) scenario, and would remain at 1.33 MBD under the "low" scenario, assuming 1975 allocation percentages. Demand analysis of the residential, commercial, industrial, utility, an non-auto transportation sectors indicates that non-automotive requirements for oil will increase under each scenario between 1975 and 1990. Regardless of scenario, the Region's automobiles will not have the gasoline required to make the 22% additional vehicle trips over the 1975 level forecast for the Region without energy constraints. Achievement of even a 6.7% increase in auto vehicle miles of travel is possible only if virtually all the Region's passenger cars are subcompacts. A technical approach for assessing the effects of the scenarios is presented, with a sampling of policy alternatives for ameliorating the situation. Among the alternatives discussed are supply rationing (coupons, restricted sale hours), price rationing, driving restrictions and disincentives (Sunday driving ban, speed restriction, carpool lanes, and tolls), and taxation.

TRANSPORTATION ENERGY CONSERVATION PLAN

A study was undertaken to define the transportation measures applicable to the northest Ohio region which can reduce fuel consumption while affecting access and mobility as little as possible, requiring low capital investment, and having the least adverse impact on the community and the environment. The project was designed to produce a set of transportation actions, to prepare a preliminary evaluation of their potential effectiveness and impacts, and to develop a handbook of methodologies. Potential transportation actions were identified and screened by the following criteria: cost of implementation and operation, responsible agency, technical feasibility, geographic applicability, public credibility, institutionl/legal barriers, implementation time, and estimates of regional energy reduction. Transportation actions included measures to increase car and van occupancy, to increase transit/paratransit patronage, to improve the flow of high-occupancy vehicles, to improve total vehicular traffic flow, to encourage walking and bicycling, to improve efficiency of goods movement, to restrict traffic, transportation pricing, and to reduce the need to travel. These potential actions were grouped into three packages to achieve three levels of energy savings, ranging from 5% to more than 15% aggregate reduction in transportation energy consumption. Further analysis and application of the techniques are recommended.

CAR POOLING SURVEY AND PROGRAM EVALUATION, WASHINGTON, D.C.

The Washington, D.C. area car and van pooling program, Commuter Club, is described. In its fifth year of operation, the program is supported by the Departments of Transportation of Maryland, Virginia, and the District of Columbia, and the Federal Hwy. Administration. Commuter Club provides car pool matching services through a computerized system. The program was evaluated by a telephone survey of applicants to determine its overall impact and effectiveness, and to discover the methods used to attract participants, the uses made of the information provided, prior mode of transportation of carpool participants, reasons for forming carpools, community benefits, and attitudes of applicants toward the program and carpooling in general. The survey indicated that 15% of those responding were assisted by Commuter Club in entering carpools. During the program's tenure, 63.5% of respondents had entered a carpool at some time. Principal cited reasons for nonuse of the provided carpool information were that respondents formed their own carpools or were satisfied with an existing pool. Principal reasons for forming carpools were (in desending oder) cost savings, time savings, convenience, and special parking privileges. Comments on carpooling and on Commuter Club were over 80% favorable by those still carpooling and only slightly less favorable by others. Average auto occupancy was 4.1 persons per pool, average duration was 23.2 months, trip length averaged 10 miles, and travel time averaged 35 minutes. Nearly half the respondents had driven alone before carpooling; only 25% had changed from transit. Economies due to Commuter Club were estimated at 48-58 million miles, 4.0-4.9 million gallons of fuel, and $7.0-$8.5 million in user operating expenses. Reduced pollution was estimated at 1315-1578 tons of carbon monoxide, 96-115 tons of hydrocarbons, and 77-92 tons of nitrogen oxides. A copy of the survey questionnaire is appended.

TRANSPORT INSITITUTIONS AND ENERGY CONSERVATION

The institutional factors and issues are explored which affect the amount of progress toward implementing energy conserving transportation actions. Illustrative transportation actions are tabulated under three categories: those degined to facilitate travel by modes other than automobile; those intended to increase the energy efficiency of auto use; and actions intended to discourage auto use. The apparently slow response by institutions to policy initiatives encouraging energy conservation in transportation is due in part to lack of consensus about the length and seriousness of the energy crisis, to a belief that conservation measures have minimal benefits, and to a lack of funding for transportation agencies. It is concluded that the usual recommendations for speeding up response to energy conservation implementation programs (publicity campaigns, funding, Federal agency coordination) are not efective and that the Federal government must insist that annual progress in conserving transportation energy be tied to further Federal aid. The transportation planning process should be well defined, with the responsible agency clearly specified, with periodic review, evaluation, and revision of experiments, and with consideration of multiple objectives.

ENERGY CONSERVATION--TECHNIQUES AND RESULTS

State and Federal efforts to conserve transportation energy are described. Tangible results are being realized from state conservation plans recently approved and in the process of implementation. Specific conservation measures mandated in state programs are right turn on red, thermal and lighting efficiency standards for buildings, promotion of carpools/vanpools and public transit, and energy-efficient state procurement practices. Some recommended significant alternative measures include 55 mph speed limit enforcement, vehicle exhaust emission inspections, implementation of transport system management plans, drag-reduction devices on trucks, and varaible registration fees according to fuel economy. Thus far, energy saving from the above measures has not represented a large proportion of overall energy savings. Price rationing of gasoline is recommended as an apolitical and effective measure. Also recommended is overcoming institutional and legal constraints to measures already approved. The need is stressed for a broad-based, aggressively implemented, overall energy conservation plan, rather than undue reliance on energy saving in one field.

THE EFFECTS OF AN EMPLOYEE TRANSPORTATION PROGRAM

The development of employee transportation programs at 3M Co. is outlined, beginning with initial programs in 1972 and 1973, which involved staggered work hours, subcription buses, Ride-Guide (carpooling) and Commute-A-Van (vanpooling). A 1974 report on personnel travel characteristics indicated that the programs reduced traffic overloads on the surrounding road networks, eased traffic flows at the 3M Center (international headquarters, eastern suburbs of Minneapolis-St. Paul), and reduced the need for additional parking at the Center. A 1977 survey indicated that the number of drivers has increased and average vehicle occupancy has decreased since 1974, but the situation compares favorably with that of 1970. The Commute-A-Van, which is described in detail, was judged successful.

TRANSPORT EFFICIENCIES AND VEHICLE OCCUPANCY RATES

Intercity and intracity travel modes in the U.S. were investigated in terms of existing energy consumption (Btu/passenger-mile), with focus on passenger loadings per vehicle for each type of modal service. The study was designed to identify methods for increasing vehicle occupancies and to determine their resulting effect on transportation efficiency. Current transportation comsumption patterns are documented followed by a series of policy choices for achieving higher vehicle loadings. The brokeage approach to higher occupancy levels for paratransit is explained, as well as for private automobile and conventional transit. The primary duty of the agent (broker) is to market programs selected by the respective jurisdictions; the programs are merged into a single implementation package, developed according to the site-specific conditions of the area. A strong marketing effort is required to raise vehicle occupancy rates. Advantages of the program are that new technology is not required and that travel preferences are unaffected.

THE NATION'S TRANSPORTATION ENERGY CONSERVATION PLAN: A CASE STUDY OF PENNSYLVANIA

Comments and evalutions are presented on the energy conservation program recommended by the Pennsylvania Dept. of Transportation in relation to the transportation elements of the Energy Policy and Conservation Act promulgated by the Dept. of Energy (then the Federal Energy Administration). The following four program measures in Pennsylvania's Conservation Plan are outlined: to promote availability and use of carpools, vanpools, and public transportation (by carpool/vanpool matching and promotion campaign, park-and-ride lots, preferential traffic control for carpoolers and transit patrons, area or facility tolls); to permit right turn on red after stopping; to increase enforcement of 55 mph speed limit (fines and penalties, public education); and to increase motorist awareness of efficient vehicle operating techniques by initiation of a public education campaign aimed at 16-19 year old students in high school driver education courses, existing drivers, and fleet drivers for private companies. The following energy saving estimation methodologies were surveyed: those of the Federal Energy Administration, Pennsylvania's procedures, and demand elasticities procedures. A synthesis of these and other methodologies has elicited four sets of forecasting variables: policy variables, behavioral factors, traffic variables, and energy consumption. These variables were combined in an evaluation formula from which the following conclusions were drawn: the total transportation energy savings from Pennsylvania's Conservation Plan is in agreement with these parallel calculations (although a consistent annual figure would be about 30% lower); a 5% national energy demand reduction for transportation seems reasonable; Pennsylvania's total transportation energy saving is estimated at about 80% of Pennsylvania's share of this reduction. The proportion of energy saved by promotion of carpools and vanpools is somewhat conservative. There is no reduction included for trips by an automobile left at home due to public transportation programs. Areas of profitable further research are outlined and further potential transportation energy conservation measures are recommended, such as increased bicycling and walking, fuel price increases to reduce demand, traffic restrictions, mass transit subsidies, and encouragement of railroad electrification.

A TECHNIQUE FOR THE ASSESSMENT OF THE FUEL-CONSERVATION POTENTIAL OF A GROUND TRANSPORTATION SYSTEM

A study was made to devise an implementable procedure for estimating the fuel saving potential of a transportation modal shift (from private automobile to public transportation). Since the procedure is designed to be used in emergency situations, only readily available data are used in a formula involving excess transit capacity and potentially divertable trips in a case study approach. A case study of Kansas City, Kans. is used for illustration. For an estimate of excess transit capacity, the "expansion factor" (ratio of the maximum number of person-trips a transit vehicle can carry to the total number of seats available in the vehicle) concept is quite practical. Parameters developed from transit system constraints and comprehensive origin and destination (O-D) survey data were used to define "potentially divertable auto trips." Further research is recommended to develop a modal split model based on total possible transit riders, to develop transit ridership market estimation schemes, and to develop emergency contingency plans for intracity mass transit during fuel shortages. Improved data collection and recording operations are recommended in transit rider usage (O-D), passenger counts, and car registration-composition tabulations.

THE ROUGH ROAD TO MAKING OIL AND GAS FROM COAL

The production of oil and gas from coal is discussed in terms of the technological and economic factors involved in meeting the 1980 synthetic fuel goal of 1.5 million barrels per day. The overall costs of such a program are estimated between $60 billion and $80 billion, with individual plants priced between $2 billion and $5 billion. Actual costs may be higher, since the estimated are not based on actual plant experience. Basic coal gasification technology dates from before 1813, and the extraction of fuel grade products has been feasible since 1936 using the Fischer-Tropsch procedure. The development of coal gas as an alternative to natural gas has failed in the United States due to rising construction costs and protracted litigation. Coal liquification to produce methanol could be directly competitive with methanol production from natural gas. Mobil Oil Company has developed a procedure to convert methanol (or any alcohol) to high octane gasoline at a pump price of approximately $1.60 per gallon. Four second-generation liquification techniques seem to have the best prospects for commercialization: the two "Solvent Refined Coal" methods being pursued by Gulf Oil and the Southern Company, which would yield mostly fuel oil and naptha; the "Exxon Donor Solvent" method, which would yield similar products; and the "H-Coal" method, which would yield boiler-fuel substitute and a lighter range of liquids. Production and plant construction, due to the large capital outlays involved, will almost certainly be geared to proven technologies such as the Fischer-Tropsch and Lurgi methods. A separate section (Industry Rediscovers Two Old Fuels: Low- and Medium-BTU Gas," by Pamela Sherrid) notes the renewed use of low and medium BTU gas to replace natural gas in various heavy industries (e.g. Caterpillar Tractor).

BIOMASS: THE SELF-REPLACING ENERGY RESOURCE

The energy potential of biomass (trees, plants, crops, farm and forest residues, algae, seaweed, and garbage) is assessed. Despite its current popularity, ethyl alcohol derived from corn presently consumes 1.6 to 2.7 BTU'S of energy for the production of each BTU of energy output. U.S. corn production would have to be increased 50% to provide a ten % alcohol additive to the gasoline currently used. Techniques for distilling ethanol from wood, grass, wastes, and other materials are not sufficiently developed for production, although wood is a viable biomass source for both direct combustion and ethanol extraction. The U.S. Forest Service estimates that forest production could be doubled with proper management, and that wood could account for as much as 6% of U.S. fuel needs by the end of the century. Problems associated with forest biomass include the inefficiency of harvesting techniques, the relatively high cost of methnanol distillation (65 cents per gallon), and the high cost of methanol plant construction. The euphorbia, a relative of the rubber plant, produces a hydrocarbon latex which can be made into oil; experimental figures indicate the plant could yield 30 barrels of oil per acre per year at $20 per barrel. Other promising sources are the gaint kelp, which yields methane, and the water hyacinth, which cleans domestic waste water and can be harvested to produce fertilizer and methane. The Dept. of Energy reports that municipal solid waste can provide a larger feedstock for ethanol than all agricultural wastes and surplus crops combined.

MATERIALS IN THE '80 MODELS

In order to meet corporate average fuel economy (CAFE) standards of 20 mpg, U.S. automakers have achieved significant weight reductions in the 1980 models through the development and use of lighweight materials. Ford has pioneered the use of graphite-fiber reinforced plastics in certain air conditioner mounting brackets and has used die-cast magnesium in steering column assemblies, mirror system components, and distributor diaphragm housings. Conventional plastics are now widely used in tailgates, heater-core end tanks, and differential cover plates. New plastic compositions have been introduced in bumpers, van hoods, and removable roof panels. In-mold-coated (IMC) plastics will improve the surface characteristics of hoods, fenders, and roof panels on the Corvette, and will eliminate the need for surface sanding during fabrication. American Motors Co. has developed injection-molded fender flairs for the Eagle, and Chrysler has produced an energy-absorbing plastic front bumper system for the Mirada. Aluminum is used for the die-cast Ford automatic overdrive transmission case, as well as for pistons in the Pontiac 4.3 liter V-8, the differential housing and supports in the Corvette, and the wheels and body panels in a variety of models. High strength steel will be used for a number of body panels and structural members, and powdered metals will be applied to transmissions, starter systems, and clutch assemblies. Stainless steel will be used in emissions-exhaust components. Coated and galvanized materials will be applied to a number of body and floor components. A separate section ("Seatmakers Take A Back Seat To No One," by Al Fleming) notes the development of new, lightweight steel, aluminum, and plastic seats, including more comfortable passenger car and truck seats.

HOW BRAZIL'S RAISING CANE OVER GASOLINE. TARGET: 100% ALCOHOL FUEL BY 1990

Since 1975 the government of Brazil, through its Proalcool program, has promoted the production and use of alcohol as an alternative to gasoline. Most Brazilian cars presently operate on a mixture of low-octane gasoline and 20% ethyl alcohol, with some government and fleet vehicles operating on pure alcohol. Government incentives to increase the use of alcohol include tax relief for alcohol fuel, restricted weekend gasoline sales in certain areas, and 36 month financing for alcohol-powered car purchases (vs. 12 month financing for gasoline models). Fiat Automoveis S. A. began marketing a 1300cc 147 series sedan designed for the exclusive use of alcohol fuel in July 1979. Although initial models are marked for public agency and fleet use, it is estimated that there will be 100,000 alcohol vehicles by 1980 and 300,000 by 1983. Brazil's automakers have the capacity to produce 100,000 to 200,000 alcohol vehicles per year, and the national alcohol output has increased from 359 million liters in 1975 to 2.6 billion liters in 1978. The 1980 goal of 4 billion liters will indicate that 20% of automobile fuel requirements are being met by alcohol. Achievement of the 1985 goal of 30 billion liters (and elimination of gasoline) will require 1070 new distillaries and the planting of 1% to 2% of the total land area with sugarcane. Technical problems to be met include the conversion of nation's fuel-dispensing equipment and the development of effective "cold-start" mechanisms for alcohol vehicles. A separate section ("The Politics of Proalcool") reports on an interview with Sahid Fahrat, Brazil's minister of social communication.

NEW-CONCEPT ALL TERRAIN UNDERCARRIAGE DESIGNED

A new concept for a universal all terrain undercarriage (ATU) has been developed by Standard Manufacturing Co. The ATU is a wheeled undercarriage with no exposed axles or differential. It can be adapted to a wide range of carried equipment with a gross vehicle weight range of 7260 to 45,360 kg. The ATU offers good ground clearance and maneuverability over improved or rough terrain. The basic ATU is made up to two identical and interchangeable side frame assemblies. Each side has three axles but more can be added if required. The axles located on the ends are higher from the ground than the center axles. This allows the center axles to carry a larger portion of the gross vehicle weight than the end axles. The combination of the center axle carrying a greater load plus the center wheels basically rolling in a circle when the vehicle is counter-rotating reduces the total skidding effect. Less turning power is required because the turning resistance is reduced. All three axles are jointly chain driven from a common gearbox (or boxes). Any wheel or combination of wheels can receive full power in the event one or more of the wheels on that side is off the ground. The gearbox is driven by a hydraulic motor coupled with a failsafe brake. The hydrostatic effect of the drivetrain system is used as the normal service/working brake. The structural frame is an all-welded tubular box section structure with integral axle supports. The drive chains, sprockets, and axle bearings operate internal to this enclosed box section in an oil bath. The carried equipment support structure can be welded directly to the side frame structure or bolted to the support pads.

CONTINUOUSLY VARIABLE TRANSMISSION HAS HIGH POWER DENSITY

Vadetec Corporation's mechanical continuously variable transmission with power density sufficient for motor vehicle use is described. The special traction drive transmits power over a speed ratio range from 0 to 1:1. It opens possibilities for new driveline types in piston-engined vehicles, and also for powertrains based on gas turbines, flywheel hybrids, and electric hybrids. The Vadetec design is based on the kinematic principle of nutation, the wobbling precessional motion of a body as it rotates about its axis: hence the term "nutating traction drive" (NTD). It has the capacity to transmit greater torques than were considered possible with traction drives, thus achieving power densities required not only for cars, but also for off-highway vehicles. In the NTD, rolling contact motion for high traction coefficients is provided by nutation of a roller member within a stationary reaction member. The unit is made up of five basic components: a transmission case or reaction member, an input or driving member, a nutating or rolling assembly, two control rings or reaction members, and an output or driven member. Detailed schemata and descriptions of the NTD are provided, and two possible gear arrangements are described. Advantages to the NTD include: a maximum Hertz stress in the rolling contact areas of 300 ksi; a capacity for instantaneous response to variations in torque; and a lack of sensitivity to variations in component dimensions. The NTD has fewer than 150 parts and can be easily manufactured. It yields high power densities, and a peak efficiency of 94% has been achieved.

CHEMICAL RADICALS PROMOTE TWO-STROKE SELF-IGNITION AT LIGHT LOADS

Scientists at Toyota and Nippon Soken have encountered a form of self-ignited combustion while studying two-stroke engines under light loads. It was found possible to dispense with spark ignition, improve fuel economy, and decrease hydrocarbon emissions while maintaining highly stable combustion conditions. This type of combustion, dubbed Toyota-Soken (TS) combustion, occurs at low pressure and temperature, is unrelated to "dieseling", and is shown to be related to the formation of chemical radicals in the combustion chamber. Studies were conducted on uniflow and Schnuerle type crankcase scavenging engines. In conventional spark ignited combustion, burning is initiated at a point near the spark plug and spreads radially throughout the chamber. With TS combustion, ignition occurs nearly simultaneously at many points near the combustion chamber center, the flame front spreading rapidly in all directions. TS combustion duration is shorter than conventional, and has been studied via Schlieren photography, which showed that nuclei for TS combustion are not generated from combustion chamber wall contaminants, as with dieseling or run-on. Thus, TS combustion can easily be achieved, even with a "green" engine. Ignition is possible due to the optimal utilization of the heat at the boundary contact layer formed between residual gas and fresh mixture in the combustion chamber. It is reasonably presumed that the CHO., HO2., and O. radicals may be generated by chemical cracking of unburnt components in residual gases or the fresh mixture existing at the contact boundary with that residual gas. Concentration ratios of such radicals could not be measured, but it is significant that these three radicals serve as ignition nuclei for TS combustion The pressure at which TS combustion occurs is 82.6psi; the temperature is 580C. The temperature-combustion range, however, can be increased to include lower temperatures and pressures by increasing radical concentration.

OFF-HIGHWAY FIRE PROTECTION: CURRENT TRENDS

Dry chemical and halon fire suppression systems for off-highway equipment are described, and consideration is given to fire detection, fire control, and fire suppression equipment. The large size of off-highway equipment aggravates the fire hazard problem by increasing the potential for fires, obstructing an operator's view of the fire, and restricting egress from a vehicle during the fire emergency. Automatic fire detection and suppression systems are available to meet various requirements of different off-highway equipment. The typical vehicle fire suppression system uses ABC, all-purpose dry chemical (monomonium phosphate). Self-cleaning nozzles have demonstrated the ability to remain clear of foreign matter that tends to obstruct discharge and change operating characteristics of a fire suppression system. A stored pressure unit has been designed with dry chemical extinguishant and propellant gas stored in the same container to prevent caking. This system can be activated by local manual control, remote manual control, an electromechanical control head, or a multiple electric device. Dry chemical systems are good when enclosure integrity is poor or nonexistent and residue is not a problem. Small pre-engineered halon systems are available when certain equipment areas are not suitable for dry chemicals (electrical equipment compartments, drag lines, shovels, and blasthole drills). These systems are pressurized with nitrogen and can be mounted vertically or horizontally to save space, using a bent siphon tube. All releasing mechanisms mentioned for dry chemical systems apply to halon systems, but instead of depressing the main check valve, the pilot check valve is opened. Fire detectors are classified according to the fire signal to which they respond (combustion particle, flame, and thermal detectors). A control unit for off-highway fire suppression equipment, developed by researchers at the Walter Kidde Company, is noted. Some types of off-highway equipment requiring different locations and types of fire suppression are identified, i.e., dozers, haulage trucks, front-end loaders, and blasthole drills.

DIESEL-ETHANOL FUEL BLENDS INVESTIGATED

The feasibility of blending ethanol with diesel fuel to produce "diesahol" for diesel-powered farm tractors was investigated, as one of three options for fueling farm tractor diesel engines with ethyl alcohol. The other options involved substituting alcohol for the usual diesel oil, and carbureting or injecting alcohol into the intake air to supply a certain proportion of required fuel with the remaining charge being normally injected diesel oil. In studies of premixed ethanol and diesel, farm tractors were not modified or adjusted to compensate for alcohol's presence. Laboratory and field tests were designed to determine comparative engine performance characteristics when mixtures were substituted for diesel oil. Power and fuel consumption tests were run on a 1962 Ford diesel and a 1978 John Deere diesel tractor engine, each directly connected to an electric cradled dynamometer. All diesel oil-ethanol blends caused a reduction in power for both engines compared to diesel oil alone. Principal factors limiting output as ethanol content increased were lesser amounts of energy injected per cycle due to ethanol's lower heating value and the relatively poor combustion properties of ethanol in a diesel engine. Diesel oil-ethanol blends increased fuel consumption per unit of work, delayed combustion, and increased engine noise. As the fuel's ethanol content increased, thermal efficiency of both engines increased slightly under full load conditions. At 25% load, thermal efficiency decreased rapidly with increased ethanol. Noise increased with increased ethanol content. Leakage at various fittings in the fuel system and past injector plungers increased with higher ethanol content. More bubbles were observed in the return fuel line with alcohol-bearing fuel. No quantitative engine wear data were derived. Peak cylinder pressures tended to be higher for blends than for diesel oil alone.

WHAT CAUSES ENGINE AFTERRUN?

Causes of engine afterrun, or "dieseling", were studied by the Chevron Res. Corp. Afterrun is generally due to auto-ignition of the air-fuel mixture at high combustion chamber temperatures and pressures. Afterrun tendency was evaluated in a sample of 22 cars from 1972-1977 model years. Eleven cars with idle speed adjusted 200 rpm above the specified setting tended to afterrun when running on unleaded gasoline. For two cars used to determine the effect of three engine operating variables (idle speed, ignition timing, and idle mixture effects) on afterrun, idle speed was found to be the major one. Unsaturated hydrocarbons (aromatics and olefins) tended to increase afterrun severity more than saturated hydrocarbons (naphthenes and paraffins). Considering both sensitivity and aromatics, unleaded gasoline had the advantage over leaded gasoline. Retarded ignition timing and lean fuel mixtures increased afterrun, and research octane number and motor octane number affected the incidence and severity of afterrun.

EGR (EXHAUST GAS RECIRCULATION) CAN REDUCE DIESEL COLD KNOCK

Volkswagen engineers have found that high rates of exhaust gas recirculation (EGR) can reduce diesel engine cold knock by flattening the combustion pressure gradient. EGR rates required to produce this effect vary between 25-60% of the intake gas quantity. These high rates are feasible because diesel engines run at very high equivalence ratios when idling. Tests were conducted using the diesel-powered Volkswagen Rabbit. Consideration was given to the relation between emissions, noise, heat rate, and thermodynamic conditions and cold knock, and the extent to which cold knock could be reduced by throttles alone was established. EGR clearly influenced intake air temperature before compression, the state of air and combustion chamber walls at the start of injection, and ignition delay. These influences were not relevant to diesel knock; the only important factor affecting cold knock was the introduction of exhaust gas to delay the combustion process.

OIL FRICTION MODIFIERS IMPROVE MILEAGE MORE THAN VISCOSITY REDUCTIONS

Research indicates that adding colloidal graphite to engine oil yields consistent fuel efficiency improvements. In track tests conducted by Acheson Industries, three 1977 model vehicles were used to measure fuel consumption. Constant-speed fuel consumption testing involved a 1-km test run at 88.5 km/hr in each direction of the straight track section. Data were corrected to 21 degrees C ambient temperature. Two major distinctions were made among test oils: sufficient viscous differences existed among conventional multigrade oils; and there were essentially no viscous differences between comparable conventional and friction-modified oils. Except for the colloid friction modified oil, all oils were formulated with identical commercially-available components. Because conventional multigrade oils were formulated with typical additive components not known to reduce friction and without friction modifiers, they were designated nonfuel-efficient oils. Oils modified with the graphite additive were conversely designated fuel-efficient oils. Colloid friction modified oils favorably altered the boundary lubrication region of the engine cylinder wall. The piston-cylinder wall interface absorbed most (60-80%) fuel energy used in overcoming mechanical friction. At least part of this friction was viscous in the form of hydrodynamic lubrication provided by oil viscosity. Viscosity differences in conventional oils showed no consistent variations in fuel economy. The addition of one weight percent graphite in SAE 5W-30 oil gave a 6.4% improvement in fuel economy during the urban driving cycle and a 5.8% improvement during the highway driving cycle. The 5W-30 friction modified oil gave a fuel economy improvement 5.5% bette than conventional SAE 10W-40 oil.

GASOLINE SULFUR CONTROL MAY BE REQUIRED...OR SULFATE EMISSIONS PROBLEMS MAY ARISE WITH THREE-WAY CATALYST SYSTEMS

Requirements for controlling sulfur content in gasoline are examined, and treatment of fluid catalytic cracker (FCC) gasoline is discussed. The sulfur content of gasoline ranges from 30-1,000 ppm. It is a function of crude oil processed, refining configuration, and refinery operating conditions. The need to process high-sulfur crude to remove sulfur in gasoline is primarily the result of a few blend stocks. Hydrocracked gasoline is the product of a conversion process that essentially removes all sulfur. The sulfur content of FCC gasoline is a function of feed quality and FCC conversion unit operating conditions. FCC gasoline is the largest contributor of total sulfur in gasoline. Representing a large fraction of the gasoline supply, it has a sulfur content ranging from 1,000-4,000 ppm. Reduced sulfur content in FCC gasoline can be achieved by removing sulfur at the end of processing or at the FCC feed level. Hydrotreating FCC gasoline is an alternative to hydrotreating FCC feed, although the octane of FCC gasoline is substantially reduced when hydrotreated. A common way of replacing the lost octane is to reform gasoline, which converts about 10-12% of the feed into gas and hydrogen. The total process results in 5% less gasoline production. The desulfurization of light naphtha from crude distillation, at a capacity of nine million barrels per day, is estimated to cost $11 million, with operating and capital recovery costs increasing gasoline price by about 0.3 cents per gallon. Treatment of FCC gasoline should obtain a 200-ppm level of sulfur in unleaded gasoline, at a cost of $3 to $5 billion. Treatment of FCC gasoline and light naphtha should permit a 100-ppm level of sulfur in unleaded gasoline, at a cost of $4 to $6 billion.

VISIBILITY REQUIREMENTS OF WORK ZONE TRAFFIC CONTROL DEVICES. FINAL REPORT

Performance standards were developed for visibility of work zone traffic control devices, based on the general principle of driver information needs and on the specific requirement for decision sight distance. A concern among highway safety officials is that these traffic control devices are not as visible as they should be due to insufficient reflectance properties or to reduced reflectance caused by dirt. To develop performance standards, analytical exercises focused on channelization devices frequently used in work zones (drums, barricades, and panels). Existing specifications for reflectivity were reviewed, including requirements embodied the 1971 edition of the Manual on Uniform Traffic Control Devices and Federal reflectivity requirements. Information needs in work zones were evaluated, with reference to information handling zones, decision sight distance requirements for work zones (avoidance maneuver, decision and response, and detection and recognition phases), and appropriate visibility requirements for reflective devices. It is recommended that reflective devices be installed and maintained so they are visible at night under normal atmospheric conditions from a minimum distance of 900 feet (275 meters) when illuminated by standard automobile low-beam headlights.

DEVELOPMENT STATUS AND EXPERIENCE OF VARTA'S BATTERY SYSTEMS GAINED ON ELECTRIC VEHICLES TESTED IN WEST GERMANY UNDER ACTUAL OPERATING CONDITIONS

Performance data are summarized for lead-acid batteries and accessories, especially designed for electric vehicles operated in West Germany. Main targets of battery developments are improvements in specific stored energy, life, and cost. Comprehensive data have been obtained by VARTA Batteries Ltd. (Canada) on lead-acid batteries installed in electric vehicles. The experience of 150 electric vehicles after driving about 2.2 million miles indicates that power data on battery performance, battery maintenance reliability, and battery system safety are important in the economy of electric vehicles and in user acceptance. Special technologies such as central electrolyte refilling, forced cooling, and central venting are discussed. VARTA's accomplishments in reducing maintenance and improving reliability are noted. Improved technologies for motive power batteries are considered, as well as the development stage of VARTA's improved nickel-iron FENOX-battery.

EXHAUST EMISSIONS AND FUEL CONSUMPTION OF A HEAVY-DUTY DIESEL VEHICLE OVER VARIOUS DRIVING CYCLES. GMC ASTRO 95, 8V-71 NA. TECHNICAL REPORT

Exhaust emission and fuel economy measurements are detailed for a heavy-duty diesel vehicle operated over various driving cycles. Driving cycles were developed from operational data collected in New York and Los Angeles under the CAPE-21 program. In each location, data were collected and segregated for the freeway and nonfreeway operation of a 1975 model year General Motors Corp. Astro 95 tractor (cab-over-engine design with tandem rear axles and equipped with a 13-speed transmission and a 4.11 axle ratio). A data matrix relating speed, acceleration, and frequency of occurrence was prepared for each city and type of operation. The concept of chassis testing for large diesel vehicles was evaluated and exhaust emissions and fuel consumption were determined by category of operation and according to vehicle load. To verify the cycle generation technique, the sensitivity of emissions and fuel consumption to changes in driving cycles was established. The effect of linearized cycles, steady-state tests, and cold start operation was assessed. Emissions averaged 2.07 g/km for hydrocarbons, 28 g/km for carbon monoxide, and 29.2 g/km for nitrogen oxides. Fuel consumption averaged 67.7 liters/100 km. Emission levels changed with load and type of operation, but they were relatively insensitive to linearization of driving cycles and cold start operation.

EXHAUST EMISSIONS AND FUEL ECONOMY FROM AUTOMOBILES USING ALCOHOL/GASOLINE BLENDS UNDER HIGH-ALTITUDE CONDITIONS. TECHNICAL REPORT

Results of emission tests are presented for 10 passenger cars operated on fuel blends containing methanol and ethanol. The test program was designed to determine immediate exhaust emission and fuel economy changes resulting from the use of alcohol-gasoline blends under high-altitude conditions. Vehicles representing the 1973-1978 model years were randomly selected from private owners in the Denver, Colo., area. Test procedures were the Federal Test Procedure (exhaust emissions only) and the Highway Fuel Economy Test. Exhaust emission levels for hydrocarbons, carbon monoxide, nitrogen oxides, aldehydes, and unburned alcohol were measured. Fuel economy was measured and recorded using the carbon balance technique. Four different fuels were explored: Indolene Clear and blends of Indolene Clear containing 10% ethanol, 20% ethanol, and 10% methanol. Results demonstrated significant decreases in carbon monoxide emissions and slight increases in nitrogen oxide emissions. Hydrocarbon emissions were often erratic, although average values decreased slightly with an increasing percentage of alcohol in fuel. Total aldehydes and the amount of unburned alcohol generally increased with the addition of larger amounts of alcohol. Overall, fuel economy decreased slightly. Evaporative emission test results on a single vehicle indicated that greater hot soak losses can be expected with the fuel blends.

EVALUATION OF A PROPOSED COLORADO STATE INSPECTION/MAINTENANCE PROGRAM. TECHNICAL REPORT

A pilot test program was conducted to evaluate the effectiveness of a possible inspection and maintenance (I/M) program for passenger cars driven at high altitudes. In response to a request from the State of Colorado through the Environmental Protection Agency's Region VIII, the work was performed in 1978 by Automotive Testing Laboratories in conjunction with the fiscal year 1977 Emission Factor Passenger Car Program in Denver. Study vehicles were randomly selected from private owners in the Denver area. Included were 99 passenger cars for the 1977-1978 model years and 30 light-duty trucks for the 1975-1978 model years. Each vehicle was subjected to an underhood inspection and a series of emission tests before and after maintenance. Maintenance was performed at one of ten selected commercial repair facilities. Information on costs associated with various maintenance actions was collected. For comparison, data on 1975-1976 passenger cars that underwent restorative maintenance as part of the basic emission factor program were included. An additional fleet of 30 1975-1976 models, each having accumulated more than 50,000 odometer miles, was tested in an as-received condition only. Results confirmed the poor emission performance of relatively new in-use passenger cars, although 1977-1978 automobiles displayed better control than those for the years prior to confirmatory testing at high altitudes. High-mileage vehicles exhibited greater hydrocarbon monoxide emission levels than their low-mileage counterparts. Underhood inspections revealed that many vehicles had been subjected to various maladjustments, primarily ignition timing and idle mixture. Results of testing after maintenance at private garages showed that a reasonable I/M program at high altitudes can be effective in identifying higher emitters and in reducing hydrocarbon and carbon monoxide emissions levels.

EVALUATION OF WARNING AND INFORMATION SYSTEMS. PART 2. COMMERCIAL RADIO ADVISORIES. FINAL REPORT

The use of commercial radio as a means to communicate accurate and timely traffic information to motorists was evaluated, in order to determine whether traffic information derived from the Los Angeles Area Freeway Surveillance Control Project computer could appreciably improve the quality and quantity of commercial radio traffic advisories. It was felt that electronic surveillance could make information more timely. Evaluation results demonstrated that commercial radio can be used effectively to report major incident information in the case where incidents last longer than 15 minutes. Traffic information for incidents of 15 minutes or less proved to be untimely. Remote visual verification of incidents, e.g., by closed-circuit television, is recommended to improve the timeliness and quality of traffic advisories. Data charts are appended.

ENGINE DESIGN EXPERIENCES AND DEVELOPMENT OF CRITICAL COMPONENTS

Construction methods and technical performance developments illustrating progress in engine design since the 1940's are reviewed, with attention paid to critical engine components. Numerous engines for which the author had some personal design and/or development involvement and responsibility are described, as are predictive techniques and uses of specialized rig tests in piston assembly development to reduce development costs and time, and to improve engine reliability. Quality control techniques are briefly compared. The need for a greater degree of in-process control is stressed, to be developed during the 1980's, to attain improved quality levels with no concurrent cost increase. It is suggested that prime movers in use during the first two decades of the 21st century will still be recognizable as reciprocating engines, but that efficiencies will be improved by reduced friction and a more efficient response to engine load demand. Fuel resource conservation and the increasing demand for improvements in ecology and consumer protection are considered as they affect the demand for and recognition of engineers.

EXHAUST TUNING

Tuning the length of exhaust systems to benefit from natural shock waves in the exhaust is considered. To understand how shock waves work to help scavenge an engine, it is necessary for one to examine what occurs inside the combustion chamber during valve overlap, when the exhaust valve has not yet closed and the intake valve has begun to open. When the exhaust valve first opens a pressure wave immediately travels through gases in the exhaust system at a speed of 18,500 inches per second. A negative shock wave is produced which travels back through outcoming exhaust gases when the shock wave gets to the pipe exit. An equation to determine appropriate exhaust length is applied in an illustration that explains how a shock wave can be used to improve gas flow throughout an engine.

BIG TRUCKS, LITTLE CARS: RISING HIGHWAY WORRY

Controversy between truckers and individuals demanding safety curbs on large vehicles is explored. Accidents involving large trucks are frequent, and President Carter has asked Congress to approve emergency legislation requiring all States to allow trucks weighing up to 80,000 pounds on interstate highways in times of energy shortages. On the other side are government investigators, automobile groups, and state highway officials who claim that heavier trucks increase highway deaths and have accelerated the decay of roads. A National Hwy. Traffic Safety Administration (NHTSA) official reports that there is a high percentage of safety hazards found on inspection of large vehicles. The General Accounting Office notes that at least 22 percent of all loaded tractor-trailers exceed State weight limits. The chief engineer for the Arkansas State Hwy. and Transportation Dept. says that increasing maximum weight in his state from 73,280 to 80,000 pounds will decrease the life of interstate highways by at least 10 percent. He also states that fuel consumption is higher on poor roads and that there is more wear and tear on vehicles. The Illinois transportation secretary reports that higher weights will increase repair costs for interstate highways by $36 million between 1980-1983. Trucking firms, in arguing that critics have exaggerated overweight problems and safety hazards, say that President Carter's proposal is crucial, particularly for independent operators. The NHTSA is planning to propose a rule requiring lower underguards on the rear of truck trailers to prevent small cars from getting pinned beneath. Tougher standards for truck brakes, tires, and lighting are also being investigated. There is rising concern about truck speeds. Adequate safety rules are supported by many groups and individuals, including the American Trucking Assoc.

STEERING GEOMETRY: BACK TO BASICS (MOTORCYCLES)

A simple wheel model is employed to explain basic concepts of motorcycle steering geometry. In permitting the steering axis to pass through the center of the wheel disk, steering offset (distance between the steering axis and the wheel spindle) is reduced to zero. The rake or castor angle can be reduced to zero by assuring that the steering axis is perpendicular to the surface. As the steering axis drops closer to the surface, the wheel adopts a camber or inclination away from the vertical plane. Steering offset can be minimized or maximized. Fundamental aspects of four basic parameters in motorcycle steering geometry are detailed: rake, trail, offset, and rolling radius. Consideration is given to camber thrust (way in which motorcycles corner), acceptable and unacceptable displacement (increasing the moment of inertia of the steered mass about the steering axis), and factors affecting suspension (e.g., aerodynamic or inertial loads, acceleration, and braking).

COPING WITH ENERGY LIMITATIONS IN TRANSPORTATION: PROPOSALS FOR MICHIGAN. A PUBLIC POLICY DISCUSSION PAPER WITH RECOMMENDATIONS FOR STATE ACTION

This "white paper" is the result of a comprehensive evaluation of future energy resources for transportation in Michigan. Focusing on fuels, especially liquid fuels for transportation, the paper analyzes four areas of the energy dilemma: existing petroleum supplies, potential for new fuel substitutes, role of energy conservation, and economic impacts for Michigan. The study indicates that up to the year 2000 the real cost of energy will rise and its availability will decline. Net energy gains are expected to decline as well (difference between energy required to extract remaining supplies and the energy resources captured). Three basic methods for improving transportation energy efficiency include improved management of existing supplies and improved technologies, shifting a portion of travel to more energy-efficient modes, and traveling less. Alternative energy forms and automotive propulsion systems are surveyed and assessed. Probable economic impacts on Michigan are discussed, and the dual pressures of rising transport energy costs and Federal regulations on the auto industry are outlined. State action for managing Michigan's economic transition is recommended, and a mechanism for "managing change" is proposed, involving increased cooperation among Federal and state agencies.

THE EFFECT OF THE ABSOLUTE SPEED LIMIT OF 100 KM/H ON ACCIDENTS IN VICTORIA. TECHNICAL REPORT

Recent speed and accident data for Victoria, Australia, were analyzed in an attempt to evaluate the effectiveness of the mandatory 100 kph (62 mph) speed limit which was introduced in rural areas of the state in 1974. Results of analysis of rural free speed data suggest that a drop in the proportion of vehicles exceeding 100 kph occurred areawide after the introduction of the speed limit. In 1975 and 1976 the trend was towards an increase at some of the 12 measurement sites. The general trend in reported casualty accident frequencies was towards a decrease in 1974, with a subsequent increase in 1975 for both "high" (subject to mandatory speed limit) and "low" (subject to long-established lower limits) speed zones, both for state highways and roads as a whole. Although no causal link between vehicle speeds and accident occurrences can be established, the trends in speed over the 1973-1975 period are reflected in single-vehicle accident frequency trends in "high" relative to "low" speed zones. Contrary to expectation, personal injury severity (ratio of vehicle occupants killed or requiring hospitalization to occupants involved) increased in "high" speed zones over the three-year period. Increased enforcement and public education are advocated to achieve a greater speed limit compliance.

EFFECTIVENESS OF THE 100 KM/H ABSOLUTE SPEED LIMIT IN VICTORIA

Recent accident and travel data for Victoria, Australia, were analyzed to determine possible reasons for the short-term decline in motor vehicle occupant fatalities in 1974 (particularly among motor vehicle passengers and in rural areas), with particular reference to the effectiveness of the rural speed limit. A mandatory 60 mph speed limit for rural areas was introduced in the state in late 1973 (subsequently converted to 62 mph (100 kph) on 1 Jul 1974). It is concluded that the speed limit law was an important causal factor in the 1974 fatality decrease; but the subsequent increase in 1975 indicated that the legislation had short-term effectiveness only. This conclusion is not supported by available data on free speeds measured at 12 sites on rural highways; this information indicates that the significant decline in free speeds at most sites in 1974 was maintained at many of these sites in 1975, before returning to their original levels in 1976. Further analysis of accident and speed data on 100 kph highways, with the addition of 1976 data, is required to resolve the apparent conflict and to clarify the changes in rural fatality patters.

COMPARATIVE AUTOMOTIVE ENGINE OPERATION WHEN FUELED WITH ETHANOL AND METHANOL

Three papers are compiled on the subject of alcohol fuels for automotive applications. The first paper compares multicylinder spark ignition engine performance when operated on indolene, methanol, or ethanol. The second paper compares engine performance when operated on straight gasoline, methanol/gasoline blends, or ethanol/gasoline blends. The third paper discusses the effects of fuel-air ratio on fuel economy and exhaust emissions for gasoline, alcohol/gasoline, or straight alcohol operation.

ETHANOL IN MULTICYLINDER AUTOMOTIVE SI (SPARK IGNITION) ENGINES; A STUDY OF PERFORMANCE AND EMISSION CHARACTERISTICS RELATIVE TO INDOLENE AND METHANOL

The use of pure ethanol in conventional automotive type e gines is discussed in relation to performance and exhaust em sion results that are obtained from a reference "gasoline" a pure methanol in the same engine. The comparison was bas on all fuels operating on the same equivalence ratio. The fir ings show, in general, that ethanol gives beter fuel econor than gasoline and poorer fuel economy than methanol (on the basis of miles per million Btu). Exhaust emissions show mixed behavior. The oxides of nitrogen emission for ethanol operation was found to be between the results obtained on gasoline and methanol, i.e., higher for gasoline and lower for methanol, but closer to the gasoline results. Carbon monoxide emissions from ethanol were found to be less than the indolene and methanol results, but unburned fuel (hydrocarbons) emissions were higher from ethanol fuel in comparison to both methanol and indolene results. The maldistribution of the fuel-air mixture among the cylinders was found to be worse with ethanol when compared to gasoline, but it was better than the results obtained on methanol.

EFFECTS OF BLENDING ETHANOL WITH GASOLINE ON AUTOMOTIVE ENGINES, STEADY STATE PERFORMANCE AND REGULATED EMISSIONS CHARACTERISTICS

An experimental study was performed to determine the effects of substituting an alcohol-gasoline blend for gasoline on the steady-state performance and emissions characteristics of a carburetted, spark-ignited engine. Three fuels were tested: a base stock of unleaded gasoline (viz. Indolene), a 20% blend of methanol in indolene, and a 20% blend of ethanol in indolene. For fixed engine conditions (engine speed, fuel-air equivalence ratio, manifold vacuum, maximum advance for best torque), the performance and emissions characteristics during 20% ethanol blend operation were found to fall between those for the 20% methanol blend and those for pure indolene. When 20% methanol blend was compared to indolene data, it was found that engine torque was approximately 2% greater, there was at most an approximately 1.7% rise in brake thermal efficiency, carbon monoxide (CO) emissions were the same, and nitrogen oxides (NOx) and flame ionization detected (FID) hydrocarbon (HC) emissions decreased. It is concluded that for the same engine conditions, the substitution of practical levels of alcohol blends (10% to 15% by volume) will have little effect on steady-state performance and CO, FID HC, and NOx emission characteristics.

VARIATIONS IN AUTOMOTIVE ENGINE PERFORMANCE AND EMISSIONS WITH CHANGES IN AIR/FUEL RATIO WHEN OPERATING ON ALCOHOL FUELS

The effects of variations in the fuel-air ratio (F/A) on engine performance and regulated exhaust emissions of hydrocarbons, carbon monoxide, and nitrogen oxides (NOx) are discussed for internal combustion engines operating on gasoline, alcohol/gasoline, or straight alcohol fuel. Switching from strictly petroleum-based fuels to alcohol or alcohol blends will alter the F/A in a fashion similar to that of adjusting the carburetor. On an equal equivalence ratio basis, straight alcohols will appreciably and favorably alter NOx emissions and engine thermal efficiency, compared to gasoline. With alcohol/gasoline blends, these same characteristic changes are roughly proportional to the percent alcohol content. For a 10% alcohol/90% gasoline blend, levels of regulated emissions and fuel economy are not significantly different from those of gasoline. In terms of engine operation, materials compatibility, and overall vehicle performance, the differences between ethanol and methanol are inconsequential.

THE EFFECTS OF FUEL ECONOMY MANDATES AND TAXES ON DRIVERS: IMPACTS BY INCOME GROUPS

Costs for automobile ownership and operation are estimated for various income groups (U.S.) based on the types of cars owned by the families in the group, the use patterns of the cars, the average length of ownership, and the average purchase age of the cars. Costs of depreciation, maintenance, insurance, and gasoline are examined. The effects on the new car market of Federally-imposed fuel economy mandates, fuel economy taxes, and gasoline taxes are investigated with the aid of an economic model simulating the profit-maximizing behavior of the domestic auto industry. The model estimates and projects the equilibrium changes in prices, costs, sales, profits, individual and aggregate fuel economy, and governmental revenues under various levels of fuel economy mandates and taxes to be imposed for 1985. In terms of direct effects on car owners and drivers, little difference is found between the mandate and the gas guzzler tax; a 50 cent gasoline tax would more than double the impact of the mandate alone. Although the imposition of any of those policies would change driving costs by only a few percentage points or less, the merit of each policy should be determined by an evaluation of its indirect effects, implementation costs, and gasoline conservation potential.

ROUTING AND SCHEDULING OF SCHOOL BUSES BY COMPUTER

An automated school bus routing and scheduling system is presented which has four basic components: input, routing, scheduling, and output, in addition to the school starting and ending time component. The key aspects of the data preparation procedures are explained, including the ministop concept, a new and innovative method for network data coding. The core algorithm is explained for each component, followed by the modifications required to implement the theoretical procedure. Implementation of the procedure in two school districts has resulted in about a 20% cost savings in one and the transportation of 600 additional students with one extra bus in the second.

A METHOD OF ESTIMATING THE FREE SPEED DISTRIBUTION FOR A ROAD

A simple procedure was developed for estimating free speed distribution (speed adopted by drivers if not influenced by the presence of other vehicles) by measuring speeds of vehicles passing a point. The method can be used even when there is substantial interference between vehicles. The procedure requires identification of vehicles traveling at speeds less than their free speed. Criteria for defining such impeded vehicles are described and compared, using data from the M4 motorway (in West London, England). The estimation procedure and time headway and relative speed criteria were applied to obtain free speed frequency distributions for near- and off-side lanes of the M4 roadway. Estimates of mean free speed are compared with those obtained from a linear regression of average speed against flow. The estimation procedure is particularly suitable for application when the number of overtaking maneuvers on a road is small. For two-way roads, which usually have a number of overtaking vehicles, it can be assumed that the vehicles are queuing and can be assigned the speed of the vehicle being overtaken. The main difficulty with the estimation procedure is the necessity of defining impeded vehicles.

A STRATEGY FOR DISTANCE CONTROL OF MOTOR VEHICLES

For the situation of driving behind a slower moving vehicle, the kinematic differences between the approaching and the following range were compiled and analyzed. Measurements of the traffic flow were carried out on a highway with two lanes in each direction. With the results of these observations and on the basis of the car following theory, a strategy was developed for distance warning indicators built into motor vehicles. An important advantage of the strategy lies in the fact that a driver is already warned at relatively great distances if he is approaching a preceding vehicle at a markedly higher speed. If he decreases his speed so that it does not differ more than 2 m/sec from that of the preceding vehicle, he can approach it (due to the less strictly conceived strategy of the following range) until he reaches the warning limit of the following range. The chosen strategy consequently prescribes an approaching speed. The effects of the warning indicators on road capacity have been calculated. For maximum traffic volume, mean distances increase while mean speeds change little (while there are no visible changes in traffic flow at lesser traffic volumes). Especially in the range of higher traffic volumes in which rear-end collisions represent the most frequent highway accident type, traffic security can be favorably influenced by distance warning indicators.

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) MOTOR VEHICLE FACTS AND FIGURES '79

Comprehensive statistical data on the U.S. motor vehicle industry documenting history and trends are tabulated and graphed. Energy, light and heavy trucks, industrial energy, emissions, safety, customer satisfaction, and government regulation are covered in an overview of the industry during the 1970's. Production and registrations statistics cover facilities of motor vehicle manufacturers, factory sales, fuel consumption, parts and accessories, production, recreational vehicles, registrations, retail sales, retirement, records, and thefts. Use and owners statistics include drivers, emissions, fleets, government ownership, highway fatalities and injuries, highways, intercity travel, ownership, personal transportation, purpose of usage, school bus transportation, shipment of goods, and vehicle miles of travel. Economic impact statistics are provided for businesses, employment, exports and imports, financing, Gross National Product contribution, Highway Trust Fund, material consumption, payrolls, personal consumption expenditures, sales, taxes, and truck sizes and weights. A subject index is provided.

POSSIBLE REFINEMENTS IN THE INTERNAL COMBUSTION ENGINE FOR IMPROVEMENT OF ITS EFFICIENCY (MOGLICHKEITEN DER WEITERENTWICKLUNG AM OTTOMOTOR ZUR WIRKUNGSGRADVERBESSERUNG)

Test results from engine development work at BMW are presented which demonstrate the potential to improve the fuel efficiency of the internal combustion engine to make it more comparable with that of the diesel engine, especially in the lower partial load range. The need to determine the most favorable compromise among number of main crankshaft bearings, bearing size, and oil pump power required in order to reduce fuel consumption is discussed. The necessity of further reducing the dependency of oil viscosity on temperature is demonstrated. The possibility of auxiliary equipment to rapidly heat the engine and its oil and water (e.g., exhaust gas heat exchangers) is mentioned for reduced friction and increased fuel efficiency. Various options are examined for the reduction of cycle losses in the partial load range by replacement of the throttle control. Expensive equipment such as variable intake control devices show comparatively little improvement. The utilization of exhaust gas energy in complicated re-expansion procedures is not very promising. In contrast, the cylinder shutdown procedure offers considerable improvement in fuel efficiency. The unthrottled ventilation of the shutdown cylinder seems an attractive possibility because of its relatively low extra cost.

AN EMPIRICAL ANALYSIS OF BEHAVIORAL INTENTIONS OF SINGLE-OCCUPANT AUTO DRIVERS TO SHIFT TO HIGH OCCUPANCY VEHICLES

A behavioral modeling framework is used to represent a conceptual structure of linkages among subjective factors relevant to traveler decision making. This analysis is designed to uncover factors which influence the intentions of single-occupant auto commuters to switch to buses and carpools, and to suggest operating policies consistent with encouraging the use of high-occupancy vehicles. The single-occupant auto commuters are segmented into several potential ride-sharing markets, on the basis of their expressed intention to take a bus or a carpool if certain transportation system modifications were effected. Three groups of switchers are identified: those who are positively oriented towards taking a bus, those who would only switch to a carpool, and those who would consider either of the ride-sharing modes. Bus convenience is the most important variable associated with the shift intention. Perceptions of carpool comfort do not appear to be as important as those of carpool schedule flexibility, cost, safety and a short wait in traffic. Additional models involving mode satisfaction are reviewed, and policies which enhance bus convenience and minimize waiting in traffic for carpools are suggested to recruit the potential ride-sharers.

EVALUATING THE PERFORMANCE OF A SIMULATION MODEL (TRAFFIC ANALYSIS)

A framework is described for the examination of mathematical models, where model calibration and evaluation are based on the ability of a model to generate a set of observed outputs from a supplied set of observed inputs. With refinement and development, the framework may lead to general structures for the more rigorous evaluation of models. An application of the proposed framework to a local area traffic assignment model is described. The application facilitates the description of the framework and some of its technical components. The traffic model was tested with peak period traffic data collected in an inner suburban area of Melbourne, Australia, during 1974. On the basis of the tests conducted, this model seems a potentially useful tool for use in small-area traffic analysis. The suggested evaluation framework has its roots in previous work in the areas of transportation, hydrology and mathematical statistics. A series of levels of model evaluation is defined. For models calibrated on their ability to reproduce observed phenomena, conclusions about model usefulness and applicability need to be made with some caution. It is necessary to investigate goodness-of-fit of model outputs, and the robustness of parameter estimates, with data independent of those on which the model was calibrated. A possible scheme, known as "dual-sample testing", is outlined for this investigation. A number of possible tests of model outputs and possible systematic errors are also discussed.

HS-027 074

EFFECT OF VEHICLE SIZE AND ENGINE DISPLACEMENT ON AUTOMOBILE FUEL CONSUMPTION

Analysis of Environmental Protection Agency data on 1977 model year automobiles shows that the rate of fuel consumption increases roughly linearly with car weight. This is largely the consequence of engine size, which is proportional, on the average, to the 1.8th power of the weight. Increased consumption due to larger engine size is partially offset by a specific engine efficiency that improves linearly with increasing engine size. The specific consumption, measured as gal/(cu in-lb-mi), is inversely proportional to engine displacement. It is suggested that sacrifice of body size (i.e. weight) to obtain improved overall fuel consumption is only one possible tradeoff; an alternative such as sacrifice of performance while retaining size might be more acceptable to one segment of the market.

A GRAPHICAL EXPLANATION OF THE TWO PRINCIPLES AND TWO TECHNIQUES OF TRAFFIC ASSIGNMENT

The interrelationships among the average, marginal, total, and integral forms of the travel time (cost)-flow function are discussed. The choice of the appropriate form of the travel time (cost)-flow function depends on the assignment technique (heuristic loading or mathematical optimization) and the assignment principle (user-optimizing or system-optimizing) adopted for use. A table is provided as an aid for this choice. A graphical explanation is presented, based on the fundamental two-route, single-demand assignment problem, to illustrate the usefulness of the graphical approach for simple analysis of various issues related to traffic assignment. This approach has been used for the basic analysis of a combined traffic assignment/control problem. The effects of differences between perceived and actual travel times (costs) can be easily demonstrated with the aid of the fundamental diagram. The diagram can also be used for such purposes as defining an equilibrium region instead of an equilibrium point for user-optimizing assignment by developing travel time (cost) curves for each route, and for studying road pricing and toll effects.

HS-027 076

THE INVESTIGATORY STOP OF MOTOR VEHICLES IN NEW MEXICO

New Mexico and other courts in the U.S. have recognized that certain situations present "exigent" circumstances which make it impracticable for law enforcement agencies to obtain warrants. With or without warrants, police officers must have probable cause to execute searches and seizures (i.e. reason to believe that the items sought are connected with criminal activity and that the items will be found in the place to be searched). In many cases where a warrantless search has taken place, the search involved a vehicle believed to contain contraband. The existence of probable cause in an emergency or exigent situation is a major exception to the warrant requirement set forth in Article II, Section 10 of the N. Mex. Constitution and the Fourth Amendment of the U.S. Constitution. In the 1977 State vs. Ruud and State vs. Galvan cases, the N. Mex. Court of Appeals took a strong position towards increasing scrutiny over police conduct in investigatory stops of automobiles. Both decisions found police officers to have acted improperly because they made stops based on a "hunch" or "intuition". In the State vs. Bidegain (1975) and State vs. Bloom (1977) cases, the N. Mex. Supreme Court reversed similar decisions by the Court of Appeals (although the decision in State vs. Bloom was based not on the propriety of police action but rather upon the power of the appellate court to review trial court findings). Although the immediate future of investigatory stops seems linked to the Galvan test, the courts may eventually begin to rely more greatly on the "field intuition" of the police officer. This poses a challenge to the protection of constitutional rights.

EVALUATION OF MOTORCYCLE SAFETY HELMET USAGE LAW. FINAL REPORT

The impact of the change to a modified (permissive) motorcycle helmet usage law from the mandatory usage law in Texas was evaluated in terms of motorcycle accidents, injury severity, and fatalities. Several data sources were utilized comparing pre- and post-law change periods: motorcycle accident records, medical data on motorcycle accident victims, questionnaires from motorcycle accident victims, and traffic counts. Supplemental data on vehicle registration, licensed operators, accident occurrences, injuries, and fatalities were obtained to establish trends, and information on helmet usage research in other states was studied. Analysis of the data revealed that post-law-change accident injuries had a 52% probability of being more severe than the pre-law injuries. The probability of sustaining a fatal injury was 2.5 times greater for the unhelmeted vs. the helmeted rider. The probability of fatality due to head injury was found to be 1.8 times as great for unhelmeted as for helmeted cyclists. When motorcyclists are given freedom of choice regarding helmet usage, it is found that a majority will choose not to wear a helmet.

FIELD TESTING A TRUCK ESCAPE RAMP

A special truck escape ramp was designed and constructed i
the Siskiyou Mountains on a section of Interstate 5 north of th
Oregon-California state line. The escape ramp is constructed o
a descending grade and is comprised of an aggregate arreste
bed, 1200 ft. long, 26 ft. wide, and 18 in. deep. It was construct
ed at the same -5.5% grade as the main line and is mostl
tangent, and to the right of the downhill shoulder. A 12-f
service lane (paved) separates the bed from the roadway shoul
der, and an oversized jersey-type concrete barrier lines the righ
edge of the bed. The entry on the uphill end and the return o
the downhill end of the arrester bed are paved. Factors leadin
to the escape ramp's development, testing procedures used fo
its evaluation, some preliminary findings on its effctiveness, in
formation on material requirements of the gravel bed, bed main
tenance procedures, and instances of actual use of the ramp ar
reported. Test results indicate that the ramp is adequate fo
vehicles and loads of the type tested (5-cu-yd trucks and
semitrailer, unloaded and loaded) entering the bed up to 8
mph, provided that the gravel bed is not frozen to a significan
depth. Tests and recent use confirm that the smooth arreste
bed can decelerate vehicles safely and without damage. Prope
signing must be provided to prevent motorists from misusing th
ramp, and to clearly identify the ramp entrance to ensure
runaway vehicle's uniform entry to the ramp.

DRINK, DRIVE AND DIE! THEN ASK US TO DEFINE "ACCIDENT"

The question of what constitutes an accident for the purposes c
applying the language of an insurance policy is discussed i
terms of a recent judgment by the Supreme Court of Canad
and a review of some previous Canadian lawsuits involvin
insurance companies, which illustrate various interpretations c
"accidental". The voluminous case law on the meaning of "acc
dent" had developed two important basic propositions whic
arose for discussion in the recent judgment in Mutual of Omah
Insurance Co. vs. Stats. In some of the cases, the courts entar
gled the definition of "accident" with the question of causatio
and the problem of determining "proximate cause". A numbe
of judgments had established that loss would not be "acciden
tal" when the insured had so deliberately or so recklessly ex
posed himself to the peril insured against as to be said to hav
"courted the risk". In the Stats case (1978), Evelyn Isobel Sta
was the beneficiary of $25,000 from an insurance policy held b
her sister Helen Brown. Ms. Brown died as the result of
traffic accident in which she drove across a sidewalk an
crashed into a building. An autopsy of Ms. Brown produced
blood alcohol reading of .19 and a urine alcohol reading of .2
Although judges in the case agreed that Ms. Brown was "gros
ly intoxicated" and "grossly impaired", judicial opinion wa
divided whether death resulted from "accidental bodily inju
ries". The trial judge dismissed the claim saying the death r
sulted from self-induced impairment and from Ms. Brown's d
cision to drive in a condition which she must have known wa
likely to lead to serious self-harm. Three judges of the Ontari
Court of Appeal were unanimous in allowing the appeal by th
claimant. In the Supreme Court of Canada, the insurer's appe
was dismissed by a bench of five, with one dissent.

APPLICATIONS AND USE OF TRANSPORTATION DATA

Seven papers are compiled which individually cover the following aspects of transportation data collection and use: field data collection and sampling procedures for measuring regional vehicle classification and occupancy; research in the Seattle area on techniques for monitoring automobile occupancy; Georgia's evaluation of Federal Hwy. Administration procedures for estimating urban vehicle miles of travel; U.S. Census travel data for transportation planning; workplace interviews as an efficient source of travel survey data; design of small-sample home-interview travel surveys; and use of travel diaries in collecting travel data on elderly and handicapped persons.

FIELD DATA COLLECTION AND SAMPLING PROCEDURES FOR MEASURING REGIONAL VEHICLE CLASSIFICATION AND OCCUPANCY

Small-scale field survey procedures that can be used to measure vehicle classification and occupancy at predeterined levels of statistical precision are described. Potential uses of these data to support activities related to transportation system management, air quality, energy efficiency, validation of urban transportation planning models, and trend analysis are identified. Statistical sampling plans, including plans that use the results of parallel traffic-monitoring programs, are presented to enable local planning agencies to design cost-effective field surveys. Representative values for key sampling parameters based on previous surveys, which are needed to use these sampling techniques, are provided. These procedures are then applied to a problem of survey design that demonstrates that regional occupancy can be precisely measured through the use of a small field survey. If percentage of trucks and truck travel are used, a relatively larger sample of field surveys is required to produce highly precise estimates.

TECHNIQUES FOR MONITORING AUTOMOBILE OCCUPANCY: RESEARCH IN THE SEATTLE AREA

Vehicle-occupancy studies were conducted in the Seattle, Washington area in an effort to develop low-cost techniques for monitoring changes in vehicle occupancy that would be sensitive to variables of season, time, and commuting distance, and then to test several hypotheses relating to variations in automobile occupancy parameters. Vehicle-occupancy counts were taken at 18 sites in the Seattle region over a 15-month period, and statistical techniques for measuring car occupancy were developed. The data were snythesized by computer and anlyzed statistically to determine whether patterns existed among sites or over time or distance. No predictable patterns or trends were found in automobile occupancy by type of facility, traffic volume, level of transit service, distance to the Seattle central business district, month or season, day of week, or time of day. This finding contradicts initial hypotheses that patterns did exist that would make an abbreviated count program sufficient for measuring changes in occupancy. Variables which might hold promise for future efforts include the income level of the commuter shed for particular sites, and characteristics of ride sharers in a corridor (whether they are coworkers, kiss-and-riders, etc.). To accurately assess changing commuting patters, a long-term, continuing program should monitor carefully selected sites at regular intervals, perhaps monthly. Occupancy rates should be plotted regularly so that any variations can be seen in the context of changing external circumstances (transportation system strategies). In the Seattle area, 9 of the 18 sites have been chosen for an ongoing program.

GEORGIA'S EVALUATION OF FEDERAL HIGHWAY ADMINISTRATION PROCEDURES FOR ESTIMATING URBAN VEHICLE MILES OF TRAVEL

The methodology for estimating vehicle miles of travel (VMT) was evaluated as described in the Federal Hwy. Administration's (FHWA) Guide to Urban Traffic Volume Counting. Comparisons were made, using the Savannah, Georgia, area, with the current method used by the Georgia Dept. of Transportation (GDOT) to calculate VMT. GDOT currently operates 61 continuous-count and 96 seasonal-control stations throughout the state that provide trends and factors used in expanding 24-hr coverage counts to estimates of average daily traffic. Approximately 25,000 of these counts are collected annually on all highways classed functionally above the local system. A random 5% sample of local county roads and city streets is obtained in counties scheduled for reinventory of physical road characteristics. The present study found that the FHWA research methodology cost 111.78% more than Georgia's conventional method and yielded only a 3.48% difference in the VMT estimation. The FHWA Guide approach of sampling links in various strata selected randomly to account for spatial and temporal variations, provides a uniform, systematic method for computing VMT. The temporal variation can be addressed in a less costly manner with only a minor variation in results. Factors of temporal variation are readily available from continuous-count and seasonal-control programs currently maintained in most states. It is desirable to use counting locations that are randomly selected by functional classification to allow for spatial variation in computing VMT.

TRAVEL DATA FROM THE U.S. CENSUS: A NEW FOUNDATION FOR TRANSPORTATION PLANNING

The travel data to be collected during the 1980 U.S. Census of Population and Housing is restricted to commuting, which represents a minority of households' daily trip making. The journey-to-work data will include work destination, "usual" means of travel, and average travel time. Although this information, if properly collected and coded, will provide an excellent means of estimating overall commuting patterns within an urbanized area, it leaves some significant gaps in the types of work-trip data commonly used by transportation planners. Trip frequency and work schedules, believed to be essential items for all urban areas if census commuting data are to be used properly, could be obtained from a sample of employers. A survey of commuters could provide additional data that would be extremely useful in analyzing commuting patterns: alternate mode, land use at destination, and mode of access to transit. Nonwork travel data, if desired, must be obtained through locally sponsored surveys. As valuable complements to the 1980 census data, the following types of transportation facility measurements are recommended in 1980: regional vehicle travel, central-area cordon count, onboard transit survey, and parking inventory. The main opportunity presented by the census seems to be that of establishing a foundation for a continuing data base on commuting. By using the 1980 census journey-to-work data to estimate home-to-work interchanges by mode for each zone in a region, the most expensive part of such a data base can be minimized. Identifying local changes in work locations after 1980 and surveying workers at these new sites can provide an affordable method of detecting change since 1980 and updating the census data.

WORKPLACE INTERVIEWS AS AN EFFICIENT SOURCE OF TRAVEL SURVEY DATA

Experience from two travel surveys of workers in the Washington, D.C. area conducted through the cooperation of employers indicates that this technique has some major advantages over more traditional home-based personal interviews. In addition to cost increases, other problems in personal surveys include the increased difficulty of finding adults at home and higher nonresponse rates because of privacy and security problems. With the cooperation of over 400 employers, 10,000 questionnaires were distributed to D.C. workers concerning the Metro rail rapid
transit system. The response rate compared quite favorably wit
that of personal surveys on similar subjects, and the costs wer
a mere fraction of those for a survey in person. Small businesse
and retailers showed a lower rate of cooperation in distributin
the questionnaires than other firms if there were no follow-up
Once employers received the questionnaires, the response rat
of workers in small businesses were actually much higher tha
that in larger firms. An apparently successful measure for in
creasing the response rate is to make the employer responsibl
for collecting completed questionnaires.

DESIGN OF SMALL-SAMPLE HOME-INTERVIEW TRAVEL SURVEYS

The following steps in designing small-sample home-intervie
travel surveys are addressed: decide on survey purpose, decid
on variables to be measured, decide whether a home-intervie
travel survey can adequately measure the variables, determi
the coefficients of variation of the variables, decide on an acc
racy level and a confidence limit, and compute the sample siz
based on the previous two steps. Methods for using stratifie
sample frames are also discussed. The techniques are illustrat
by using composite data from several urban areas. It is show
that 900 to 1200 home interview samples are sufficient to dev
op a cross-classification model for trip generation based
automobile ownership and income, depending on whether
simple random or multistage sample is taken. It is shown th
for the purpose of travel demand forecasting, this sample size
sufficient for calibrating trip-distribution and mode-choi
models. For traffic assignment modeling, the size of the surv
is relevant only to the extent that an accurate trip table can
simulated. Computation of the required sample sizes is based
average measurements of variability taken from several are
around the country; the coefficients of variability can be co
pared to find the required sample size where the procedures
to be applied.

USE OF TRAVEL DIARIES IN COLLECTION OF TRAVEL DATA ON THE ELDERLY AND THE HANDICAPPED. ABRIDGMENT

A survey incorporating the use of travel diaries by elderly
handicapped persons was conducted as part of an evaluation
a user-side-subsidy demonstration project to be implemented
Lawrence, Massachusetts. Before the travel diary was filled
each participant was administered a background questionna

that included questions on past travel behavior, and individual and household characteristics. The trip information requested in the diary included origin, destination, travel mode, trip purpose, and start time. From preliminary analysis of the diary data, obtained in the "before" survey, tabulations of average daily trip rate by household income and car ownership show the expected relations. Weekly tabulations show the decline in the rate of travel from the beginning to the end of the month that is typical of travel among elderly and handicapped individuals. The entire sample of travelers averaged 99 total monthly (one-way) trips with a mode of 60. An initial estimate of the standard deviation in total trips is 60, or about 60% of the mean. Only 38% of all trips were "return to home", implying that 24% of trips were links in a travel chain, and that at least 30% of all round trips had multiple destinations. Although not all respondents to the survey have joined the user-side-subsidy project, the same proportion have registered as in the population at large, or about 25%. The total cost of the diary survey was $24,000. For the 285 completed one-month diary surveys and the 315 sociodemographic and retrospective travel questionnaires, these costs represent approximately $77/usable diary and $6/usable survey questionnaire.

TURBINE WITH A NEW TWIST. GOODBYE TO PROBLEMS WITH EMISSIONS, MILEAGE AND DRIVABILITY?

A new automotive turbine engine, the Kronogard Turbine/Transmission (KTT) system, differs from conventional automotive gas turbines in that it has three vs. two stages. Through an ingenious system of planetary gears, the third-stage turbine supplies auxiliary power to the turbines in the first two stages; it also drives the accessories (fuel and oil pumps, alternator, etc.) with energy that would otherwise be wasted. The ceramic turbine wheels are about 25% smaller than in other types of automotive gas turbines of similar power. Since they have less inertia, they accelerate faster; the power turbine has a maximum speed of 70,000 rpm. The third turbine and associated planetary gearing allow the KTT to achieve twice the stall torque possible with other automotive turbines. A KTT-POWERED Volvo test car drives as easily as a standard Volvo with automatic transmission, and is smoother. Starting takes 5 sec longer, but there are no cold-starting problems. No tuneups or oil changes are required. In actual road use, a Volvo with a KTT Mark I engine, running on diesel fuel, averages 20 to 24 mpg. For the Mark II, estimates run as high as 30 mpg with all-metal rotors, and up to 40 mpg with some ceramic materials in the hot-zone rotor system. Lab measurements of KTT exhaust gas show a potential for meeting the Environmental Protection Agency research goals of 0.41 g/mi hydrocarbons, 3.4 g/mi carbon monoxide, and 0.4 g/mi nitrogen oxides, as well as a future 0.2 g/mi limit on particulates. The KTT system is under development at United Turbine Co. (Malmo, Sweden), which was formed by the inventor, Prof. Sven-Olof Kronogard, in 1974, and is partly owned by Volvo.

THERMAL MANAGEMENT OF THE LITHIUM/METAL SULFIDE (BATTERY) ELECTRIC VEHICLE

Thermal management studies of the lithium-aluminum/metal sulfide battery have demonstrated the need for a lightweight, highly thermal-efficient case for electric vehicle batteries. Proposed conceptual designs for the battery case employ vacuum-foil insulation and meet design requirements determined in the management studies. A preliminary comparison of cylindrical vs. rectangular configuration for a 50 kW-hr battery showed significant advantage for the former, provided that cells can be so configured without significantly impacting cell manufacturing cost or performance. Thermal analysis calculations, which have been completely based on the rectangularly-configured Mark IA battery, indicate that the heat loss goal of 400 W should be easily met. The calculated value of 283 W suggests that, with further design refinements, the goal of 150 W heat loss for the 50 kW-hr Mark II battery is attainable. Experiments directed at determining the reversible (TdeltaS) heating experienced by cells during electrical cycling showed an average value of 0.104 W/A which compares well with a calculated value of 0.112 W/A based on theoretical considerations. Mark II battery calculations indicate that using the thermal storage capacity of the battery between 420 degrees C and 450 degrees C permits a duty cycle based on 10,000 mi/yr, requiring essentially no additional energy to keep the battery hot.

MINIMIZING THE WEIGHT OF ALUMINUM BODY PANELS

Alloy selection and/or geometrical design guidelines that lead to least-weight aluminum body panels for automobiles are described. Performance criteria influencing inner and outer body panel geometry and thickness include denting, local stiffness (oil-canning of outer panel), torsional/bending stiffness, strength, and vibration. The use of high-strength alloys provides the least panel weight when the governing criteria are denting, permanent set, and crippling. Redesign to change panel span or rib size and shape provides the least weight when the governing criterion is stiffness. Any performance criterion can control design. For example, a plot of an aluminum assembly's relative weight as a function of yield strength shows that the highest relative weight occurs when stiffness governs design, and that the least weight occurs if design is limited by denting. Designers should use high-strength alloys to their fullest strength levels for minimum weight so that dent resistance and/or permanent set are the controlling performance criteria.

A HIGH ENERGY TUBULAR BATTERY FOR A 1800 KG PAYLOAD ELECTRIC DELIVERY VAN

This high-energy lead-acid battery was developed to provide, at no extra cost, an 1,800-kg (4000 lb) payload electric delivery van with a driving range of 80-90 km (50-55 miles). A prototype vehicle designated the Dodge Silent Karrier Mark 1 was constructed in 1975. Technological advances in tubular plate manufacture made thin plate batteries viable. Thin plate technology was the essential precursor to the long-life, high-energy, motive power battery needed to provide credibility to the electric vehicle program. Battery specifications, cell development goals, and system parameters were established. In addition to high-performance electrodes, an integrated approach to the total power source concept evolved lightweight designs for battery packaging, a system-engineered battery charger, and an automatic topping-up facility. Despite the 40% improvement in range compared with 55-65 km (35-40 miles) for conventional traction batteries, a 4-year battery life can be reasonably expected due to reinforcing features of the tubular design adopted for positive electrodes.

REINFORCED REACTION INJECTION MOLDING PROCESS AND MATERIALS FOR AUTOMOTIVE BODY PANELS

The reaction injection molding (RIM) process is used extensively for the production of soft urethane bumper fascias and offers many advantages compared to other polymer processes. The concept of adding fiber reinforcement to a urethane substrate has resulted in significant improvements relative to stiffness and dimensional integrity while maintaining a low specific gravity. With the proper combination of reinforcement and urethane chemistry, a damage-resistant material suitable for automotive body panel applications can be expected. An investigation of reinforced reaction injection molding (RRIM) equipment and material is underway at General Motors. A description of the RIM process is given, various reinforcement particles described, and the equipment and procedure distinctions of the RRIM process are detailed. Consideration is given to length and loading limitations, equipment wear and durability, bulk handling and blending equipment, and physical properties of the RRIM product. Areas needing further development are examined, and potential automotive applications based on the RRIM process are discussed.

CONTROLLING THE PHYSICAL PROPERTIES OI RIM (REACTION INJECTION MOLDING) URETHANES WITH NON-ORGANIC REINFORCEMENT

Work done since June 1977 at the Goodyear Tire and Rub
Co. demonstrates that physical properties of reaction inject
molding (RIM) compounds can be modified to meet cert
requirements by the selection of reinforcement type and conc
tration. The use of RIM materials in exterior automotive s
tions has limited application due to the high coefficient of lin
thermal expansion (CLTE), and poor heat resistance. Incorpo
tion of a reinforcing agent in RIM material (reinforced react
injection molding or RRIM) improves these properties wh
retaining the excellent processing qualities of RIM. The RR
process follows the pattern of the standard RIM process, i
high-pressure metering and impingement mixing. Due to
abrasive nature of high-viscosity glass-filled RRIM compone
certain machine modifications are required. The Cincinnati
lacron LRM-G machine used in Goodyear's work incorpora
the following features to permit the use of reinforcements: c
tinual low-pressure recirculation through the mix head; Lan
type cylinders; reinforcements added to both streams; and
heads built from hardened materials. Experiments indicate t
the addition of milled fiberglass or mica flake reinforceme
results in increased flexural modulus, decreased CLTE,
creased elongation, and decreased impact strength. Milled
berglass orients into the mold during injection, causing aniso
pic behavior in physical properties. Mica flake reinforced ure
anes do not exhibit orientation effects found with milled fibe
lass, but mica flake causes a greater reduction in elongation
impact than milled fiberglass. Several urethane systems are c
sidered, and general effects of mica flake or milled fiberglass
found to be reasonably independent of the base urethane syst

HIGH-STRENGTH STEEL SHEETS FOR AUTOMOBILE BODY PANELS

The overall suitability of various sheet steels (strain-aging st
such as capped nitrogenized and rephosphorized steels
killed rephosphorized and microalloyed steels) for automo
body panel applications is assessed by comparing their resp
tive characteristics for formability, weldability, and paintabil
Steel sheet formability is perhaps the most important requ
ment for body panel applications. To minimize the loss of
mability that occurs as strength is increased, steels having y
strengths of 40-50 ksi are considered primary candidates for
in body panels. Of the different types of 40-50 ksi steels
viewed, killed rephosphorized steels (especially a silicon-c
taining version) show the best combination of formability
weldability. Although some difficulty in meeting paint and
formance requirements has been reported with these steels, a
tional study is needed to identify factors affecting paintability
killed rephosphorized steels. The application of cold-rolled d
phase steels is discussed, along with material requirements
body panels.

REINFORCED POLYESTER IN THE EUROPEAN AUTOMOTIVE INDUSTRY

The feasibility of using plastics as a metal substitute on vehicle bodies and parts to minimize weight is explored. The situation in Europe is detailed, particularly the chances for fiberglass-reinforced polyester. Automobile material selection is affected by the oil crisis, the shortage of raw materials, and energy-saving and anti-rust legislation. Factors of value maintenance, recycling, and environmental protection are important, and plastics have good prospects in this regard. Thermoplastic materials should be considered for parts such as doors, hoods, trunk lids, and removable roofs. Reinforced polyester shows the most potential, but four considerations must be taken into account. The peculiarities of the vehicle manufacturing industry include the need for sufficient lead time in development of vehicle prototypes, the need to retool plants, and the need to coordinate development with allied industries. The political significance of the decision to use reinforced polyester on a large scale, will affect many aspects of vehicle safety legislation. Collaboration among raw material producers, paint manufacturers, machine developers, and assembly and transport specialists must be coordinated. Finally, the effect of reinforced polyester use on the labor force and the economy must be assessed.

INNOVATIVE SHEET MOLDING COMPOUND PROCESSES

The contribution of lightweight sheet molding compound (SMC) to vehicle weight reduction in accordance with the Federal mandate for gas mileage is evaluated. For SMC to be competitive with other improved lightweight materials, several changes in the quality and productivity of the standard compression molding process must occur. At General Motors Mfg. Devel., the objective of the Plastics Process Devel. Dept. is to improve this process. Work covers updating the programmable force velocity control system, the molded coating system, and mold heat transfer analysis. A Class "A" surface SMC product with less finishing operations can be achieved with molded coating. Heat transfer analysis will shorten the cycle time and eliminate part warping by uniform curing. A more consistent and/or advanced SMC composite can be attained with the SMC equipment mix room/inline system and advanced SMC machine. The advanced compression mold transfer line will permit high productivity of a given SMC part. Concepts to be investigated in further work focus on SMC equipment and an advanced compression mold transfer line.

A FUEL CONTROL SYSTEM FOR 0.4 NOX (OXIDES OF NITROGEN)

Factors affecting the control of nitrogen oxide emissions are addressed, with reference to fuel economy and drivability. Most studies question or deny the ability to design and develop a system that will maintain 0.4 grams of nitrogen oxides per mile. A careful review of factors affecting emissions and fuel economy and available control systems, however, suggests that the 0.4-gram objective may not only be achieved but exceeded. Advanced sensing, control, and exhaust after-treatment may achieve superior performance without sacrificing fuel economy and drivability. Vehicle downsizing and sophisticated system control concepts may retain achievements despite more stringent fuel economy standards. The real challenge for a fuel control system occurs during transient operating conditions. Testing with a 4,500-lb 1978 Cadillac, having a factory-installed electronic fuel injection system modified to operate in the sequential injection mode, indicates emissions improvements of hydrocarbon (28%), carbon monoxide (43%), nitrogen oxides (17%), fuel economy improvements of 5.5%-7.5%, and excellent drivability. It is anticipated that the development of a closed-loop fuel control system with the ability to adjust adaptively to changing environment, plant, and hardware conditions will result in even better emission control.

AN ATTENUATION AND TRANSPORT DELAY MODEL FOR SINGLE POINT CLOSED-LOOP FUEL METERING SYSTEMS

A fuel modulation attenuation model for single-point closed-loop fuel metering systems is presented. The model calculates the attenuation of a metered air-fuel perturbation and the time delay in the transport of perturbed signals from the metering point through the engine to the exhaust system as a function of modulation frequency, engine RPM, intake manifold vacuum, and exhaust gas recirculation. Results for a V-8 engine with sine wave, triangular wave, and square wave modulations show that attenuation for the triangular wave is highest, and for the square wave is smallest. In general, attenuation increases with increasing modulation frequency and increasing exhaust gas recirculation, but decreases with increasing RPM. The model can be extended to study the attenuation and transport delay of other engines and wave forms. Sine wave modulation equations are appended.

STUDY OF THE EFFECTIVENESS OF REDUCED VISIBILITY GUIDANCE TECHNIQUES. VOL. 2, EQUIPMENT SURVEY. FINAL REPORT

Equipment needs of reduced visibility guidance (RVG) systems were evaluated in this 1977 survey that covered five equipment categories (fog sensors and monitors, vehicle sensors, signing, reduced visibility guidance and delineation, and communication equipment). The goal was to determine what system design factors contribute to system effectiveness and what approach is economically feasible for specific highway conditions. Data were collected and analyzed for seven reduced visibility systems. A utility-cost model was generated to allow quantitative comparisons. A measure of need index was also derived to make comparisons between hazard seriousness levels at different locations. Information was provided by equipment manufacturers and distributors; additional data were obtained through a literature review and contacts with principal equipment users and researchers in the field. The survey resulted in a methodology which allows reduced visibility problems to be quantified and permits resources to be allocated in a systematic way proportionate to hazard seriousness.

A PEDESTRIAN PLANNING PROCEDURES MANUAL. VOL. 2, PROCEDURES. FINAL REPORT

Significant data, procedures, and criteria for consideration in the planning and evaluation of comprehensive pedestrian systems and individual facilities are identified. This manual is operational and sequential in nature, with procedures grouped according to two major phases: the demand modeling phase, where existing and projected pedestrian movement is examined using a gravity model approach to produce a network plan that shows the assignment of pedestrian volumes; and the network evaluation phase, where the first phase output is utilized to develop a plan that addresses specific planning aspects of a pedestrian system and modal interface requirements. Methods are incorporated for examining and evaluating system effectiveness and potential impact. The need for a pedestrian planning process, the pedestrian planning context, and application of the pedestrian planning process according to a step-task approach are reviewed. Tables, figures, and mathematical equations are included.

PASSING AND NO-PASSING ZONES: SIGNS, MARKINGS, AND WARRANTS. FINAL REPORT

Criteria, warrants, and traffic control devices are suggested
use in designing safe passing operations and designating
passing zones on rural two-lane highways. Criteria are base
vehicle performance during the passing maneuver, on the p
ise that sight distance should be provided at the critical pos
when passing and passed vehicles are abreast, and on evalu
of traffic control devices in providing required visual info
tion at this critical position. Minimum passing sight distan
defined as the sight distance necessary at the critical positio
permit a passing driver to perceive an opposing vehicle in
to complete the passing maneuver safely. An advance pave
marking system comprised of a short dotted yellow line
cent to the roadway centerline throughout the pass compl
distance is proposed, in conjunction with a no-passing
pennant sign, to advise the passing driver that beyond that
there is not sufficient distance to complete the maneuver b
reaching the no-passing zone. Warrants for no-passing zone
presented, with lengths of advance treatment and minimum
tances between successive no-passing zones for a range o
pected operating speeds. An economic analysis of nation
system implementation indicates a high probability of cost-
tiveness. Use of the single solid yellow centerline on rural
lane highways to designate restrictive passing zones is eva
ed, based on driver understanding tests, accident rate com
son, and opinions of personnel from various fields (enginee
enforcement, and legal) regarding expected safety and co
ance problems.

PEDESTRIAN ACCIDENTS OCCURRING ON FREEWAYS: AN INVESTIGATION OF CAUSATIVE FACTORS, ACCIDENT DATA COLLECTION AND ANALYSIS. VOL. 2. FINAL REPORT, PHASES 3 AND 4

Data on 236 accidents involving pedestrians struck on limited access highways in California, Michigan, Missouri, North Carolina, and Pennsylvania were collected and analyzed. The data included behavioral sequence items, accident location characteristics, identification items, pedestrian factors, driver factors, and vehicle factors. Accident investigations were intended to identify precipitating and predisposing factors in each accident. Data reduction and analysis resulted in the identification of characteristic accident situations or types. Although 14 different accident types were observed, the most frequent types accounted for nearly 60% of accidents (disabled vehicle, result of auto-auto crash, unusual circumstances, hitchhiking, interchange dash, and walking to or from disabled vehicle). The relatively infrequent occurrence of pedestrian accidents on freeways, less than 1,000 annually nationwide, and varied causal factors involved such as suicide, alcohol, poor weather, and disabled vehicles, suggest that countermeasure implementation be carefully considered on a site-by-site basis. Countermeasures intended to minimize each accident type are discussed.

EPA (ENVIRONMENTAL PROTECTION AGENCY) NOISE CONTROL PROGRAM--PROGRESS TO DATE

Activities of the Environmental Protection Agency (EPA) in carrying out the Noise Control Act of 1972 and the Quiet Communities Act of 1978 are reviewed. Under the Noise Control Act, EPA was mandated to identify and regulate major sources of noise, propose aircraft noise standards to the Federal Aviation Administration, label noisy products, engage in research technical assistance and public information dissemination, and coordinate Federal noise control efforts. The Quiet Communities Act significantly increased EPA'S role in helping States and localities to establish noise control programs and in providing the public with information about the harmful effects of noise. EPA is developing noise abatement plans for various modes of surface transportation (highway and rail) and the areas they affect. Noise emission standards and regulations have been established for wheel and crawler tractors (construction equipment), truck-mounted solid waste compactors (garbage trucks), motorcycles and motorcycle replacement exhaust systems, buses, truck-transport refrigeration units, power lawn mowers, and pavement breakers and rock drills. Federal noise program coordination is discussed. Special EPA projects and studies are noted, and a publications list is included.

FACTORS CONTRIBUTING TO THE DECREASE IN MOTOR-VEHICLE FATALITIES FROM 1973 TO 1977

In late 1973 and early 1974, the gasoline shortage led to a 55-mph national maximum speed limit. There was an immediate decrease in motor vehicle fatalities, as the National Safety Council (NSC) had predicted before the law went into effect, that lasted beyond the shortage period. NSC studies in 1975 disclosed that the 55-mph law acted as a catalyst and helped produce general reductions in speed on low-speed and high-speed roads. Reduced speed accounted for approximately 50% of the reduction in fatalities during 1973-1974. In 1977, four years after the 55-mph law, reduced speed was still a major factor in keeping the death total low. Factors contributing to the decreased death total were long-term trends in the mileage death rate, reduced speed and narrower speed distribution, extra use of interstate highways, and reduced average occupancy (fewer people at risk). Factors serving to increase the death total were changes in motorcycle use, changes in the age distribution of drivers, and increased use of small cars. Overall, 12,600 lives were saved from 1973-1977 with introduction of the 55-mph speed limit. Savings were also realized in gasoline consumption.

DRINKING AND DRIVING ACCIDENTS--DOES EDUCATION HELP?

The contribution of problem drinkers to road accidents is considered, and the role of publicity and education in minimizing drinking-related accidents and in maximizing law enforcement is explored. In England, persons with very high blood alcohol concentrations who are involved in accidents and repeat offenders cannot have their drivers' licenses restored until they satisfy the courts that they have reformed their behavior. The worst accidents dealt with by a typical London casualty department are caused by people returning from parties late at night who drive at high speeds. Drinking and driving legislation passed in 1967 by England's Department of Transport was accompanied by massive publicity. Attempts were made to encourage public awareness, but there is no evidence of an impact on accident rates. Fear of detection is the best deterrent, particularly when people realize there is a genuine chance of a breath test. Publicity and education are essential in making people aware of alcohol's effects on driving. Without more accurate knowledge of attitudes, however, publicity and education may not be effective. Attitudes can be evaluated in roadside surveys. The importance of education, especially by road safety officials and physicians who see the results of road accidents after drinking, is stressed.

HOW TO BUY AN AERIAL DEVICE FOR A UTILITY TRUCK

Factors to consider in the purchase of powered manlift or aerial devices for utility trucks are described. Aerial devices vary in cost, complexity and size from a simple truck-mounted ladder to 150-foot devices mounted on crane carrier chassis. Considerations pertinent to aerial device purchase are height of work to be performed, insulation, load to be lifted, required side reach, travel height, number and span of outriggers, and whether the unit should articulate fully, be overcenter, non-overcenter, or a telescoping boom. Ease of maintenance is also a consideration. Articulated units often give a better choice of working positions and facilitate field side work. Telescoping units are generally preferred when working through heavy trees. The purchase of a device larger than required can waste capital, both in the device itself and in the chassis required to mount the device. Purchasers should be aware of Federal (Occupational Safety and Health Administration), state, and local standards applicable to aerial devices, as well as standards promulgated by the American National Standards Inst.

SIMULATION OF AN URBAN BATTERY BUS VEHICLE. FINAL REPORT

The computer simulation of a battery-powered bus as it traverses an arbitrary mission profile of specified acceleration, roadway grade, and headwind is described. Battery-bus system components include a DC shunt motor, a solid-state power conditioning unit with regeneration capability, and a battery source consisting of a multi-unit lead acid battery. The computer model determines vehicle tractive effort and power consumption and computes actual vehicle speed for a given mission profile. Program output data are tabulated in a form permitting easy recognition of various operational modes and power-limited regimes. The computer model uses a modularization format which facilitates the simulation of alternative propulsion systems involving the interchange of one system component for another. The model is applied to simulate propulsion characteristics of a typical bus operating over a specified drive cycle. Results demonstrate the applicability of the battery-bus model for predicting bus propulsion characteristics under simulated drive conditions. A glossary of program constants and variables is appended.

ANALYSIS OF LIFE-CYCLE COSTS AND MARKET APPLICATIONS OF FLYWHEEL ENERGY-STORAGE TRANSIT VEHICLES. FINAL REPORT

Flywheel energy storage systems have been proposed as a means of reducing energy requirements of fixed-route, multistop, urban transit vehicles. A study was conducted to assess lif cycle costs and potential applications of these vehicles in urba transit operations. Two conventional concepts (diesel and tro ley buses) and three flywheel vehicle concepts (all flywhee flywheel/diesel, and flywheel/battery buses) were compared. present worth costing procedure was used to express life cycl costs of each vehicle system in equivalent 1977 dollars. Wit this technique, the present value life cycle cost was determine by discounting all expected fixed capital and annual recurrin operations and maintenance costs over the investment perio Energy consumption, potential demand, and market applicatio were evaluated. Present value costs per vehicle mile for trolle and all flywheel vehicles were inversely related to assume vehicle density on the route. Per vehicle mile costs of dies flywheel/diesel, and flywheel/battery vehicles were not affecte by changes in vehicle headway. The flywheel/diesel vehic offered an 8% energy savings over the baseline diesel bus, whi the all flywheel vehicle offered a 22% energy savings over t trolley bus. The flywheel/battery bus was a highly energ intensive vehicle, consuming nearly 31% more energy per vel cle mile operated that the trolley bus. A market share of 10 30% of the total new bus demand was projected for flywhe powered vehicle systems in the 1980-1990 period. Appended additional information on life cycle cost analysis (analysis mod and system operation equations; recent bid prices and age dist bution of diesel and trolley buses; cost estimates for overhe trolley power line and distribution system, and for flywhe propulsion units).

PAVEMENT CONDITION MEASUREMENT NEEDS AND METHODS. FINAL REPORT

A field review of pavement evaluation practices was conducted in 11 states (Calfornia, Florida, Georgia, Kentucky, Nebraska, Pennsylvania, Texas, Utah, Virginia, Washington, and Wisconsin). Each state had implemented in one form or another a program using measurements and evaluation of pavement characteristics as a basis for scheduling maintenance and rehabilitation. Data collected during the state visits, supplemented with a literature review and a limited, firsthand review of equipment in use, were used to develop recommended measurements, measurement procedures, and equipment for a complete pavement condition survey. Recommended data processing, storage, and retrieval procedures were also developed. The measurements needed for pavement condition evaluation are skid resistance, roughness, structural capacity, and distress. Appended are guidelines for discussing pavement condition measurement needs and methods with state transportation departments; an overview of state visits; summary tabulation by state of skid system features, components, and operations; test methods for roughness and deflection; data handling approach for pavement management; list of recommended equipment manufacturers; and estimated cost per mile for pavement condition measurements.

DESIGN OF A LINEAR STEP ACTUATOR (AUTOMOTIVE APPLICATION)

The design of a linear step actuator is described for an automotive application requiring a step of .1 mm for each input of DC voltage to the actuator with a total travel of 13.2 mm or 125 steps of input power. This performance was required over the usual voltage range of 9 to 15 volts, at a stepping rate from 0 to 160 steps per sec, and over an operating temperature range of -40 degrees C to plus 110 degrees C. The mechanical considerations were that the unit was to screw into a threaded hole and to mate with an electrical connection plug. A motor of the type selected for this application has been used in AC synchronous devices called synchronous inductor motors. The motor had about 6.5 nt mm of holding torque, thus giving about 4.4 nt mm of max stepping output torque.

AUTOMATED STRUCTURAL BONDING SYSTEMS FOR GRAPHITE AND OTHER HIGH-STRENGTH COMPOSITES

Structural bonding of reinforced plastics has been utilized for more than ten years in a variety of automotive applications (e.g. truck front-end assemblies, pickup box covers, utility vehicle tops), usually involving manual application of the adhesive. With the emerging interest in high-volume production of lightweight parts, new materials with higher strength are being used (e.g. graphite, high-glass, and oriented-glass systems). Newly developed uses for reinforced plastics are radiator supports, bumpers, frame cross members, doors, truck tailgates, station wagon lift gates, and truck cabs. These new applications necessitate improvements and simplification of the adhesive bonding system as well as improvement and automation of the application equipment. Some recent developments along these lines include the Goodyear Pliogrip adhesive system, Liquid Controls meter mixing equipment, and automated, three-dimensional, programmed robot equipment made by Robotics, Inc. Automated structural bonding will be most successful if the manufacturer, adhesive supplier, and equipment suppliers work as a team on a systems approach.

SOFTWARE DESIGN VERIFICATION IN REAL TIME FOR MICROPROCESSOR BASED ELECTRONIC ENGINE CONTROL

The software engineer's tools and techniques for electronic engine control strategy software development are outlined. Typical debugging techniques (the assembler program and "walk through" debugging) are mentioned. Discussed in more detail are several approaches to software design verification, each providing an additional degree of confidence with a corresponding level of effort. These techniques include emulation, time-shared simulation-emulation comparison, bench testing, vehicle testing, and computerized real-time software design verification (SDV). Primary attention is given to the time-based stimulus generation, the real-time performance measurements, time-based tolerance generation, and data reduction of a real-time SDV test system. It is highly recommended that all high-volume computer-based control systems include a real-time SDV.

THE DISADVANTAGE FUNCTION TECHNIQUE FOR OPTIMIZATION OF ENGINE CONTROL STRATEGIES

In order to determine the optimal calibration of electronic engine control systems for minimal fuel consumption and compliance with emission control standards, the disadvantage function technique was developed. Given pollutant limits, a target fuel consumption rate, the driving schedule as represented by a mini-map (a data set derived from steady-state testing at a small number of representative speed/torque points over a range of control strategies), a set of advantage and disadvantage coefficients, and an engine data base, the computer program computes an allocation of pollutants and corresponding disadvantage functions. All control conditions for a given mini-map point are ranked in order of increasing disadvantage function. The program computes the total emissions and fuel consumption for the set of "best" control conditions, given the coefficients. Through an iterative procedure, interacting with the program, the engineer arrives at a near-optimum balance. The disadvantage function technique is described, illustrated by an example, and compared with well-known optimization methods.

HS-027 126

ENGINE CONTROL OPTIMIZATION VIA NONLINEAR PROGRAMMING

A procedure is introduced for establishing optimum engine performance in terms of fuel economy and exhaust emission constraints as a function of spark advance, exhaust gas recirculation, and air-fuel ratio. The procedure is based on mathematical engine models that have been validated over a driving cycle on an engine dynamometer. It is based on solving a nonlinear programming problem with equality and inequality constraints. The results of the optimization are used to develop control calibrations that can be implemented on a vehicle. Results are presented of applying the optimal control procedure to models of a fuel-injected, spark-ignited V-8 engine under warmed-up operating conditions, assuming constant efficiency of the catalytic coverter. Vehicle validation of these results has yet to be demonstrated.

EXCESSIVE TRUCK WEIGHT: AN EXPENSIVE BURDEN WE CAN NO LONGER SUPPORT. REPORT TO THE CONGRESS BY THE COMPTROLLER GENERAL OF THE UNITED STATES

U.S. highways are deteriorating at an accelerated rate and sufficient funds are not available to meet current needs or future requirements for repair. Excessive truck weight is a major cause of highway damage. The rate of highway deterioration will slow down if excessively heavy trucks are kept off the highways. Federal weight limits and monitoring of state weight enforcement programs are inadequate to protect the $96 billion Federal highway investment made since 1956. The Congress should amend highway legislation to apply Federal weight limits to all Federal-aid highways and to prohibit issuance of overweight permits and exemptions when loads can be reduced to meet normal state weight limits. National statistics show that about 22% of loaded tractor-trailers exceed state weight limits. The Dept. of Transportation must work with the states to develop an effective weight enforcement program. Penalties severe enough to deter overweight operations should be imposed. Proposed draft legislation is appended.

HUMAN FACTORS CONSIDERATIONS IN ARROW-BOARD DESIGN AND OPERATION

Human factors are considered in the design, use, and operatio of flashing arrow boards. These factors involve the inherent meanings of arrow boards to drivers according to the display configuration, possible optimization of the display to convey the desired message, and possible optimum operation of the devices The study included a review of the literature, some limited fiel studies, and application of human factors expertise and judgments. The two experimental studies attempted to discern meanings associated with arrow-board configurations by obtainin subject responses to film clips of arrow-board operations. Th results indicate that the arrow board is strongly associated wit lane closure and that the use of an on-off blinking arrow i favored over the sequencing chevrons or sequencing arrow ster followed by the stem plus head. Arrow-board design and operation can be manipulated and optimized as long as drivers perceive a discrete, clear directional arrow as an indication of lan closure. Violation of this usage for other traffic manageme purposes leaves drivers uncertain how to behave. The preferre operation of the arrow board is by a single on-off blinkin arrow. The blinking arrow should not be used as a cautiona display only. The use of 360 degree lens hoods is required cap dispersing light to passing drivers and to direct the flashing lights outward in a straight line perpendicular to the arrow board. Dimming of luminance could be upgraded to be more sensitive to inclement weather conditions and to lesser diminution of daylight. Arrow boards should be placed at the beginning of the taper (construction zone).

EXPERIMENTAL EVALUATION OF MARKINGS FOR BARRICADES AND CHANNELIZING DEVICES

A series of four laboratory experiments was conducted to determine quantitatively the optimum design of markings on traffic control devices used in highway construction zones. The following marking parameters were studied: the design and configuration of stripes, width and color ratio of stripes, the meaning of various design configurations, and the detectability of visible areas (height to width combinations). For each of the experiments, 30 drivers recorded their detection and identification responses to stimulus slides, which were presented tachistoscopically. Data reduction consisted of analyses of a derived index score, which was a summary of the total response. It was determined that optimal stripe width is a 20- or 15-cm (8- or 6-in) stripe for 15 cm or greater rails. The desirable ratio of white-to-orange coloring favors equal white to orange or more white. Optimal stripe design configurations are first vertical, followed by horizontal. Chevrons connote directional meaning to drivers. Vertical panels elicit better performance than horizontal bars or trapezoid shapes. There was little useful difference between type 1 and type 2 barricades (single or double bar). A tall, narrow, vertical panel image is recommended over a shorter, wider device.

VISIBILITY REQUIREMENTS FOR TRAFFIC-CONTROL DEVICES IN WORK ZONES. ABRIDGMENT

A study was undertaken to develop a performance requirement or standard for the detection and recognition of retroreflective traffic control devices used in work zones (drums, barricades, panels, and cones). By an analysis of existing information and data, a performance standard was established from the principles of driver information needs and, specifically, the requirement for decision sight distance. The standard states that the reflective device shall be installed and maintained so as to be visible at night under normal atmospheric conditions from a minimum distance of 275 m (900 ft) when illuminated by the low beam of standard autombile headlights. This standard would apply to any device used for channelization purposes in the work zone.

HS-027 132

EFFECTS OF TAPER LENGTH ON TRAFFIC OPERATIONS IN CONSTRUCTION ZONES

A direct comparison was made of traffic operations using the standard and a proposed taper length in the same construction zone. The proposed taper length formula yields shorter tapers at design speeds below 96 kph (60 mph) than does the existing formula (L equals WS, where L equals minimum length of lane-drop taper, W equals width of offset, and S equals speed limit or 85th percentile speed). The alternative formula is L equals W(S squared)/60. Speed, erratic maneuvers, traffic conflicts, and centerline encroachment data were collected at four sites, day and night, for a variety of design speeds and taper lengths. Data analyses did not imply that the proposed taper lengths are more hazardous than the standard taper length. Use of the proposed length did not produce a greater number of erratic maneuvers and slow-moving vehicle conflicts than did the standard or existing taper length. There was no indication that the proposed taper lengths resulted in a greater number of passenger vehicle or truck encroachments on adjacent lanes.

EFFECT OF LONGITUDINAL EDGE OF PAVED SURFACE DROP-OFFS ON VEHICLE STABILITY

The effect of edge of pavement drop-offs on vehicle stability is reported for 50 tests of professional drivers handling small-, medium-, and large-sized automobiles and pickup trucks off, along, and back onto drop-off heights of 38 mm (1.5 in), 89 mm (3.5 in), and 114 mm (4.5 in) at about 26.8 m/s (60 mph). Tests of two- and four-wheel drop-offs were conducted from an existing asphalt concrete shoulder onto both compacted soil and ashalt concrete surfaces. The drop-off heights had little effect on vehicle stability: steering wheel angles were generally 60 degrees or less; vehicle roll angles were 10 degrees or less. A significant jolt and accompanying front-end noise were experienced by the driver at the larger drop-off heights; there were no problems with vehicle alignment. Less than one wheel revolution was required for the first wheel to mount the drop-off heights. Varying amounts of front-wheel wobble caused mainly by an irregular drop-off edge were detected. There was virtually no deviation in vehicle trajectory as the vehicles remounted the drop-off edges, and the vehicles did not encroach into adjacent traffic lanes. Two nonprofessional drivers participated in a few supplementary tests. They had no difficulties driving over all three drop-off heights at 17.9-20.1 m/s (40-45 mph). The results of these tests were used to help evaluate the California maintenance standards in effect in 1974.

FIELD EVALUATION OF TRAFFIC MANAGEMENT STRATEGIES FOR MAINTENANCE OPERATIONS IN FREEWAY MIDDLE LANES

Results are presented of field studies conducted in Houston, Tex., to evaluate the performance of two innovative approaches for managing traffic during maintenance operations in the middle lane of an urban freeway. The two approaches, traffic shifting with use of the shoulder and traffic splitting, were used by District 12 of the Texas State Dept. of Highways and Public Transportation during pavement repairs on Interstate 45. The results of the studies indicate that, compared to the multilane closure strategy commonly used at middle-lane work sites (closure of an exterior lane and one or more adjacent middle lanes), both approaches significantly increased work-zone capacity. The studies revealed that traffic shifting could be used to manage traffic at relatively long work sites on freeways with discontinuous shoulders, and that shoulder use at sites where this strategy was employed was greatly influenced by traffic demand. Traffic splitting around an isolated, middle-lane work site, on the other hand, was used effectively at a relatively short work site on a freeway section that did not have shoulders.

PEDESTRIAN ACCIDENTS OCCURRING ON FREEWAYS: AN INVESTIGATION OF CAUSATIVE FACTORS, ACCIDENT DATA COLLECTION AND ANALYSIS. VOL. 3. APPENDIXES. FINAL REPORT

Data were collected on 236 accidents involving pedestrians struck on limited-access highways in California, Michigan, Missouri, North Carolina, and Pennsylvania in an effort to identify causal factors in freeway pedestrian accidents and to develop countermeasures. The distribution of these accidents is tabulated for single field variables (related to descriptive, pedestrian, driver, vehicle, environmental, pedestrian and driver trip, site, roadway, collision, causal, and accident type factors). Copies of the data collection form and the field investigator coding manual are provided. Abbreviated descriptions are given of the various types of pedestrian accidents. Copies are included of operational forms used in the pedestrian accident survey, as well as a glossary. A Federal Hwy. Administration freeway pedestrian accidents survey conducted prior to the present project is described.

TRAFFIC STRIPE REMOVAL

Available information on methods to remove unwanted pavement markings is summarized, as obtained from various highway agencies throughout the U.S. The most frequent methods used are chemicals, grinding, high-pressure water jet, high-temperature burning, hydroblasting (sand and water), and sandblasting. A number of other burning and chipping techniques are used to a limited degree. The effectiveness of each method depends on the thickness of the marking, type of pavement, and operator skill. Both grinding and sandblasting are generally slow but effective in removing thick strips; these methods result in pavement damage when removing embedded paint. The high-pressure water jet is effective on portland cement concrete (PCC) pavements, but not as effective on asphalt. The hydroblaster can remove thicker paint stripes, is effective on PCC, and is less effective on asphalt. Chemical methods and high-temperature burning appear to offer the most economical and rapid means of removing pavement markings, but these methods are limited by marking thickness. One of the more successful approaches is the combination of two or more methods. A grinder is used to remove the marking material down to the pavement surface, followed by use of either a chemical or high-temperature burner to remove the material embedded in the pavement surface.

MOTOR VEHICLE SAFETY 1978. A REPORT ON ACTIVITIES UNDER THE NATIONAL TRAFFIC AND MOTOR VEHICLE SAFETY ACT OF 1966 AND THE MOTOR VEHICLE INFORMATION AND COST SAVINGS ACT OF 1972, JANUARY 1, 1978--DECEMBER 31, 1978

This report is submitted to the Congress on the administration of the National Traffic and Motor Vehicle Safety Act of 1966; also provided is information on bumpers, as required by Title I, Section 112, of the Motor Vehicle Information and Cost Savings Act of 1972. An introductory chapter discusses the magnitude of the highway safety problem, persistent problems, and current trends. Subsequent chapters individually cover: areas receiving substantive attention (occupant crash protection and survivability, crash avoidance, fuel economy, commercial utilization of advanced automotive technology, consumer information and vehicle recalls, and data acquisition, analysis and reporting), crash survivability, crash avoidance, standards enforcement and defects investigation, standards summary, legal highlights and administrative enforcement, special programs (international cooperation, no-damage bumper system, odometer regulation enforcement), informing press and public, research and how it is used, and administration. A glossary of acronyms is included. Appended are a statistical compilation of accidents and injuries (and other traffic safety data), funding tables, a list of National Hwy. Traffic Safety Administration publications, a list of current research grants/contracts and problems they address, and a description of litigation.

HIGHWAY SAFETY 1978. A REPORT ON ACTIVITIES UNDER THE HIGHWAY SAFETY ACT OF 1966 AS AMENDED, JANUARY 1, 1978--DECEMBER 31, 1978

This report submitted to the Congress on the administration of the Highway Safety Act of 1966, Section 202(a), also provides information on the administrative adjudication of traffic infractions and evaluation of driver education programs, as required by the Highway Safety Act of 1973. An introductory chapter discusses the magnitude of the highway safety problem, persistent problems, and current trends. Part 1 covers areas receiving substantive attention (55 mph speed enforcement, pedestrian safety, motorcycle safety, safety belt usage, and data acquisition, analysis, and reporting), safer drivers, safer vehicles, services that improve traffic safety, measures for informing press and public, National Hwy. Safety Advisory Com., international cooperation, Highway Safety Program Standards, research and how it is used, and administration. Part 2 covers highway safety within the Federal Hwy. Administration, highway safety research, and other highway safety programs. A glossary of acronyms is included. Appended are a statistical compilation of accidents and injuries (and other traffic safety data), a membership list for the National Hwy. Safety Advisory Com., funding tables, lists of National Hwy. Traffic Safety Administration and Federal Hwy. Administration publications, a list of current research grants/contracts and the problems they address, and a description of litigation.

AUTOMOTIVE MANUFACTURERS' COST/REVENUE, FINANCIAL AND RISK ANALYSIS: PROJECTED IMPACT OF AUTOMOBILE MANUFACTURING ON THE PLASTICS INDUSTRY. FINAL REPORT

Background information is provided on current and future uses of plastics in passenger automobiles and the impact of changes in the characteristics of the average U.S. automobile is assessed, particularly on the producers of plastic resins. Total U.S. plastics consumption has increased at an annual rate of 6.5% from 1969 through 1977. Plastics consumption by passenger car manufacturers has increased at an annual rate of 8.4% over the same period. While there are over 20 generic types of plastics used in automobiles, the most important, in terms of tonnage, are polyurethane, polypropylene and its copolymers, polyvinyl chloride, thermosetting polyester resins, and acrylic-butadiene-styrene resins. The plastics content of the average car will probably increase from about 80 kg in 1976 to as much as 250 kg in 1990. Much of the growth will be as a result of new applications of plastic resins in exterior and functional parts, with thermosetting polyester resins, polyurethane, and polypropylene accounting for 20% of the projected increase. Major increases in manufacturing capacity will be required for some areas, requiring a total capital investment of about $1.7 billion (1978 basis) including investment for manufacture of basic petrochemicals, intermediates, and monomer manufacture. Reports on individual plastic compounds are appended.

"STAR OF LIFE" EMERGENCY MEDICAL CARE SYMBOL. BACKGROUND, SPECIFICATIONS, AND CRITERIA

The "Star of Life" has been adopted as the medical emergency care symbol, distinct from the Greek Red Cross symbol. Its use is approved by the appropriate agency and its advisory council within the Dept. of Health, Education and Welfare. It is applicable to all emergency medical goods and services funded under the DOT/EMS (Dept. of Transportation/Emergency Medical Services) program and criteria, and is recommended for use by the States. The orgin and meaning of the design (serpent entwined staff against a blue star with six flat points) are explained, its historical background presented, and its registration as a certification mark detailed. Specifications and uses are set forth.

AUTOMOTIVE MANUFACTURER RISK ANALYSIS: MEETING THE AUTOMOTIVE FUEL ECONOMY STANDARD. FINAL REPORT

A risk analysis model of the automobile industry is developed to assess the impact of the Automotive Fuel Economy Standards (AFES) on each of the manufacturers in the industry. Data from reports written or sponsored by the Dept. of Transportation and from publicly available sources are used to illustrate the application of the model. Some insight is given into the interaction among the corporate environment, the manufacturer's strategy, and the AFES. It is concluded that the AFES tend to increase concentration in the industry, and to favor, relatively, the larger manufacturers having a full product line. Since increased numbers of small cars need to be sold to meet the AFES, larger cars become more expensive and smaller cars less expensive. Finally, several different economic and manufacturing scenarios are analyzed in detail, leading to a variety of more specialized insights. The scenarios include increased capital expenditures, no AFES, higher AFES, foreign entry into the mid-size car market, and a shift in market shares of domestic manufacturers. Three other scenarios examine economic risk.

FOUR REGIONAL WORKSHOPS ON THE NATIONAL MAXIMUM SPEED LIMIT (NMSL) AND HIGHWAY SAFETY PROGRAMS. FINAL REPORT

A series of four workshops was conducted on The National Maximum Speed Limit (NMSL) and highway safety programs, including the Federal/state role in NMSL compliance and related highway programs. Topics addressed included: a review of ongoing programs at the National Hwy. Traffic Safety Administration; the Controlled Access Highway Task Force; Non-Resident Violator Compact; CARE (Combined Accident Reduction Effort); radar detectors; roundtable discussion on 55 mph NMSL; and Highway Safety Programs. The most important and most frequent recommendations developed by these discussions were: that the President of the U.S. issue a statement supporting the NMSL and urging voluntary compliance; that funds authorized by Congress be specifically designed for use in achieving NMSL compliance, and that they be placed under the control of the state law enforcement agency; that NMSL compliance criteria be more realistic and attainable, with either a 70% compliance rate by 1982 or compliance based on median speed rather than on current criteria; that the same pressures of compliance be placed on all other agencies (i.e., courts, legislators, ect.) as those imposed on the law enforcement segment; and that Federal legislation be enacted to regulate (or provide) the manufacture, sale, and/or use of radar detectors. The activities of each regional workshop are outlined (Mountain Pacific, North Atlantic, Southern, and North Central regions). The appendices include the program objectives, a sample of the evaluation form sent to participants, the International Assoc. of Chiefs of Police resolutions, and remarks of the participants.

INTEGRATED SAFE DRIVING INFORMATION SYSTEM DEVELOPMENT. (VOL. 1.) FINAL REPORT

The development is described of an integrated system throug which states can assure the dissemination of safe driving info mation to all categories of motor vehicle operators. The Syster addresses drivers in five subsystems and 16 components withi subsystems: qualification subsystem (new drivers, reading limi ed drivers, foreign speaking drivers); maintenance subsyster (licensed drivers, older drivers, physically limited drivers, nev residents); advancement subsystem (experienced drivers); im provement subsystem (traffic violators, drinking drivers, acc dent-involved drivers); special vehicle qualification subsyster (motorcycle operators, truck and bus, school bus, recreationa vehicle and emergency vehicle operators). Development of th following project materials is discussed: The Integrated Saf Driving Information System (ISDIS) Plan; Catalog of Availabl Materials; and State Guide. Other materials prepared under th project are appended, including the ISDIS Materials Ratin System; an Experienced Driver Manual; Ambulance Drive Manual; and School Bus Driver Manual.

INTEGRATED SAFE DRIVING INFORMATION SYSTEM DEVELOPMENT: VOL. 2: SYSTEM PLAN. FINAL REPORT

The Integrated Safe Driving Information System (ISDIS), described as a plan of state and Federal activity to improve th flow of safe driving information to operators of motor vehicle For planning purposes, drivers are divided into five subsysten and 16 target groups: the qualification subsystem includes ne drivers, reading limited drivers, foreign-speaking drivers; th maintenance subsystem includes licensed, older, or physical limited drivers and new residents; the advancement subsyste includes experienced drivers; the improvement subsystem i cludes traffic violators, drinking drivers, and accident-involve drivers; and the special vehicle qualification subsystem includ motor vehicle operators, truck and bus operators, school b operators, recreational vehicle operators, and emergency vehic operators. The system plan described the information requir ments, presentational materials, delivery programs, acquisitio incentives, implementation requirements, and evaluation tec niques appropriate to each target group. Recommendations a offered to the National Hwy. Traffic Safety Administration develop safe driving materials, and to promote their availabili and dissemination. Recommendations to the states include i proving the licensing process to ensure knowledge and skill the licensed driver, raising of standards for licensing tests, a active leadership in coordinating and supporting the activities of state and local agencies in disseminating safe driving information.

INTEGRATED SAFE DRIVING INFORMATION SYSTEM DEVELOPMENT. VOL. 3: STATE GUIDE. FINAL REPORT

Activities are described which may be undertaken by states to improve the flow of safe driving information to their drivers. The drivers addressed in this Guide fall into four categories on the basis of their information needs: the qualification category, where information is needed to help drivers attain minimal qualifications for safe driving (covers new, reading-limited, and foreign-speaking drivers); the maintenance category, where information is needed to help drivers maintain their ability to drive safely (includes licensed drivers, older drivers, and physically limited drivers); the improvement category, where information is needed to help drivers improve their driving safety (covers volunteers for safe driving courses, traffic violators and drinking drivers); the special vehicle operation category, where information is needed to help drivers operate vehicles other than automobiles (includes operators of motorcycles, trucks, buses, school buses, recreational vehicles, and emergency vehicles). Methods and incentives for disseminating information are described, and available materials discussed.

INTEGRATED SAFE DRIVING INFORMATION SYSTEM DEVELOPMENT. VOL. 4: CATALOG OF AVAILABLE MATERIALS. FINAL REPORT

A catalog is provided of informational materials available to assist state highway safety agencies in disseminating safe driving information to drivers. Included in the catalog are written, audiovisual, instructional, and mass media materials. The catalog provides the title of the material, a brief description of contents, including length or duration, producer, and preparation date, and the availability of the material, including the name and address of the distributor. The Catalog is organized in terms of the target groups described in the Guide, which identifies target groups of drivers, their information needs, and ways of delivering information to them.

AN EXAMINATION OF THE COMFORT AND CONVENIENCE OF 1979 SAFETY BELT SYSTEMS. FINAL REPORT

Comfort and convenience aspects of safety belt systems in 1979 model cars were evaluated by 114 test participants in 30 test cars. The operation of the belt systems was divided into eight categories: accessibility, extending, buckling, fit, pressure, comfort (response when wearer reaches for glove box or looks out rear window), releasing, and retracting. Excessive slack in the shoulder belt, belt twisting, and improper retraction were noted during each trial. It was found that the belt systems do have varying comfort and convenience problems. The greatest problems with 1979 model cars occur when the user is reaching for the glove box or turning to look out the rear window; other problems include extending the latchplate over to the buckle, belt fit, belt pressure on chest and shoulder, and latchplate accessibility. Older users perceive fewer comfort and convenience problems. Shorter users have problems with fit and comfort, while taller users experience problems with belt retraction. Comfort and convenience ratings are not affected by subject weight and belt usage. Smaller cars have more accessibility problems. Two-door cars have more problems with accessibility, fit, comfort, and retraction than do four-door cars. Dual retractors create fewer retraction problems, while continuous loop systems cause fewer comfort problems. Bucket seats create problems with accessibility, extending, buckling, releasing, and retracting, while bench seats cause more fit, pressure, and comfort problems. Windowshade devices relieve belt pressure on shoulder and chest when properly used, but create excessive belt slack and incomplete retraction.

ALCOHOL SAFETY ACTION PROJECTS EVALUATION METHODOLOGY AND OVERALL PROGRAM IMPACT. VOL. 3

Following a background discussion of the ASAP (Alcohol Safety Action Proj.) program and a review of previous, interim assessments of total ASAP impact, a study evaluated whether the ASAP program as a whole had a statistically significant impact on the number of alcohol-related crashes. Time series techniques were applied to nighttime fatal crashes at each of the 35 ASAP sites as well as those of each of 11 matching comparison sites. Based on the individual project analyses, 12 ASAP sites showed a statistically significant reduction in nighttime fatal crashes during their demonstration period. None of the comparison sites showed any significant decreases in nighttime fatal crashes between baseline and demonstration periods. The Albuquerque and Tampa projects showed increases in these crashes, as did three comparison sites. For 27 sites which conducted roadside breath test surveys, a decline from 53 to 46 drivers per thousand with blood alcohol concentrations greater than or equal to .10% was found from the baseline to operational surveys. Of the 19 sites which conducted actual baseline surveys (vs. 8 which used the first operational survey as "baseline"), 8 were among the 12 sites which demonstrated a significant reduction in nighttime fatal crashes while the others showed no change. The cost per fatality forestalled (total ASAP program cost of $88 million (Section 403 funds) divided by 563) was $156,306. The ASAP countermeasure ranks between 14th and 15th among 37 countermeasures in terms of cost per fatality forestalled. In addition to fatality reductions, ASAP benefits include reductions in night injury crashes, injury severity, and property damage crashes, plus forestalling economic and social losses to the community. In addition to the overall results, an analysis of each ASAP is provided (project description, data graphs and tables for ASAP and comparison sites).

HOW TO DEAL WITH MOTOR VEHICLE EMERGENCIES. REVISED ED.

Some of the most common motor vehicle emergency situations are described, with information on how they can be handled. The booklet is intended primarily for drivers relatively inexperienced in coping with emergency malfunctions in their vehicles. The first rule of crash avoidance is to keep a vehicle in safe running condition; tips are given on daily and weekly/monthly checkups, and periodic servicing. Precautions to observe when stopping on the highway are outlined. The following emergency situations are individually considered: throttle sticking, brake failure, loss of steering, loss of power-assisted braking and steering, fires, loss of lights, overheated engines, loss of oil pressure, alternator/generator failure, windshield wiper failure, dropped driveshaft, hood popup, submersion of car, loss of lug nuts on wheels, exhaust system failures, flat tires and blowouts, driving through water or in heavy rain or snow, and mini-emergencies (unruly children, insects, and clothing, upholstery, and ashtray fires). A list is provided of necessary or useful items to carry in the trunk or glove compartment.

ANALYZING THE FEASIBILITY OF THE ADMINISTRATIVE ADJUDICATION OF TRAFFIC OFFENSES. VOL. 1: TECHNICAL SUMMARY. FINAL REPORT

Information is provided for use by local government analysts in conducting feasibility studies of the administrative adjudication of traffic offenses. Experiences of administrative adjudication programs (AAP) in various jurisdictions (Rhode Island, Seattle, New York City, Buffalo, and Rochester) are described, as well as an AAP feasibility study prepared by the California Dept. of Motor Vehicles for the state legislature in 1976. Issues normally addressed in a benefit-cost analysis of alternative traffic offense adjudicative systems are discussed: basic arguments for administrative adjudication, legal and constitutional issues, anticipation of special-interest-group concerns, the monetary and nonmonetary treatment of benefits and costs, and the treatment of traffic safety issues. Methods of presentation of study findings and documentation for public information are discussed along with tactical issues associated with study planning and implementation.

PASSENGER MOTOR VEHICLE ELECTRICAL SYSTEM INTEGRITY. FINAL REPORT

Results are detailed of a two-part study to examine the integrity of automotive electrical equipment and to determine the electromagnetic susceptibility of automotive electronic control systems. The design and failure modes for various electrical components and recommended corrective measures are discussed. Over 400 failed components were collected, tested and analyzed. Of these, 29% proved to be still operating within limits when bench tested. Further analysis suggested that either the symptoms might have been misdiagnosed by the mechanic, or there could be intermittent failures which the test procedures did not identify, or a failure existed related to the component but not actually within it. A second significant trend found in the study of faile components was the apparent reliability of the electronic components being employed on cars. Additional research dealt with the potential susceptibility of electronic control systems to electromagnetic radiation and the results of a measurements program designed to determine the extent of the susceptibility o three existing systems to the electromagnetic environment. Th need for electromagnetic compatibility standards is emphasized and various measurement techniques and means are discusse for setting limits in order to establish standards. Appended ar data on the design and failure mode study, control group failur data for the 12-month period, diagrams of the computer wirin harness, and schematics of special harness test boxes.

SUMMARY OF NATIONAL ALCOHOL SAFETY ACTION PROJECTS

The nature of alcohol problems and traditional drunk driving programs are described, including background on the Alcohol Safety Action Proj. (ASAP) program, a summary of the success of the program in meeting its immediate goals, and an outline of program findings. These aspects are further covered in more detail and ASAP costs and revenues are discussed. The ASAP program included 35 projects, 2-5 1/2 years in duration, which involved an expenditure of $88 million of Section 403 funds between 1970 and 1977. At most ASAP sites, police were able to double or triple drinking driving arrests. The ASAP courts developed procedures that permitted much more rapid and efficient processing of DWI (driving while intoxicated) cases while preserving traditional judicial safeguards for defendants. About a quarter of a million drunk drivers, of which two-thirds were problem drinkers, were referred to education or treatment programs by ASAP's. When compared with a fine alone, almost any type of education or treatment program appeared to improve the subsequent driving record of social drinkers. Short-term treatment for problem drinkers appeared to be less successful. Mass media programs developed by ASAP's to enlist public support proved effective in increasing public awareness of the drinking driving problem and increasing support for ASAP's. In an evaluation of overall ASAP impact, nighttime fatal crash rates for the ASAP sites were compared with those of matched non-ASAP sites. The results show that ASAP's had a modest but significant effect in reducing this type of accident, a large proportion of which are alcohol-related. A financial analysis of ASAP data indicated the potential for projects to be self-sufficient. If approximately $200 could be collected from each DWI offender (as is being done in the Virginia ASAP), the basic cost of the program could be met from this source. Some of the funds must be used to increase enforcement to ensure client flow.

MANDATORY SAFETY BELT USAGE LAWS. TASK FORCE REPORT. REV.

The feasibility and timing of implementing mandatory safety belt usage (SBU) laws in the states are examined. Past Federal efforts in restraint system usage are reviewed as well as state activities. The timing involved in the adoption of blood alcohol concentration tests, motor vehicle annual inspection, and motorcycle helmet usage legislation is reviewed to give an indication of what might be expected with enactment of SBU laws. Experiences with the motorcycle helmet use law and the 55 mph speed limit law are described. Public and safety official opinions are examined on the issue of SBU laws and foreign (Australia; Ontario, Canada; France) experiences with these laws are reviewed. Efforts to promote voluntary usage of safety belts are discussed: mass media campaigns, improvements in safety belt comfort and convenience, and use-inducing devices (warning light, buzzer). The effectiveness of SBU laws is examined in terms of fatality reduction estimates. An 80% usage rate of an improved three-point belt system (and a use-inducing system) with an effectiveness of 60% in fatality avoidance should result in a 48% reduction in the number of occupant fatalities which would otherwise occur in 1990. At a maximum, a 21% fatality reduction could be achieved in 1990 by voluntary methods without usage laws; the usage laws would account for the remaining 27%.

STATE-FEDERAL RELATIONS IN HIGHWAY SAFETY. A REPORT TO THE SECRETARY OF TRANSPORTATION BY THE NATIONAL HIGHWAY SAFETY ADVISORY COMMITTEE

On-site assessments were made of the ability of Colorado, Iowa, New York, and Oklahoma to identify highway safety problems, to select appropriate countermeasures, and to evaluate the results. The respective roles of the National Hwy. Traffic Safety Administration (NHTSA), the Federal Hwy. Administration (FHWA), and the states were examined as well. Officials contacted in the site visits were found to be knowledgeable and competent in administering highway safety program components or specific disciplines of safety. Few of those interviewed spoke in terms of managing or coordinating statewide highway safety programs, which are now fragmented and diffused among several state agencies. Many officials viewed themselves as managing merely a Federal grant-in-aid program, responsible only for those programs or projects actually funded through the Federal 402 program. It is recommended that the Secretary of Transportation issue instructions implementing the concept of a statewide Hwy. Safety Prog. administered through a State Hwy. Safety Agency via the rulemaking process of the Administrative Procedures Act. These instructions should be coordinated specifically within the National Governors' Assoc. Appropriate recommendations in the Transportation Res. Board's Report on the Role of the State Hwy. Safety Agency should be implemented. NHTSA and FHWA activities should be coordinated. The administration of the 403 Res. Prog. should be reviewed to ensure coordination with the states. The release of public information material to the mass media should continue to be coordinated with that of the states. The financial accounting system reporting on the 402 Grant Prog. should be changed to reflect the status of 402 funds within the states. State and Federal data collection systems should be reviewed by the National Hwy. Safety Advisory Com.'s Task Force on Hwy. Safety Data, and the Task Force on Emergency Medical Services (EMS) should monitor the implementation of the Dept. of Transportation-Dept. of Health, Education, and Welfare Memorandum of Understanding on Procedures Relating to EMS Systems.

AUTOMOTIVE MARKETING METHODS AND PRACTICE. FINAL REPORT

A comprehensive examination is presented of the current marketing practices, marketing methodologies, and decision-making processes utilized by the domestic automotive industry. The various marketing elements, such as products, consumer behavior, sales, promotion, distribution, advertising, and regulatory constraints are reviewed as they pertain to the automotive industry. Seven chapters specifically review industry competitive relationships, practical constraints on automotive decision-making, corporate organization for decision-making, consumer communications, marketing decision-making, assessment of current problems and issues, and state-of-the-art summary. Appendices focus on the organization of General Motors Corp. and Ford Motor Co., the product and market planning process graphics, and an example of a forward product strategy document. Where appropriate, the differences in marketing approaches employed by the four automotive manufacturers are highlighted, with some of the adjustments and problems faced by these manufacturers in their marketing pursuits.

PRELIMINARY ANALYSIS OF THE NATIONAL CRASH SEVERITY STUDY: FACTORS IN FATAL ACCIDENTS

National Crash Severity Study (NCSS) passenger car accident fatalities are compared to those in the Fatal Accident Reporting System (FARS), as a tool for evaluating NCSS data representativeness. Estimates are computed of the probability of fatality for NCSS for various conditions (i.e. fire incidence, occupant sex). In cases where two factors are highly correlated, such as rollover and ejection, modeling techniques are used to help quantify the effects of each variable. It is found that FARS and NCSS have similar distributions of many variables: urbanization, vehicle size, vehicle damage, occupant seating location, sex, and restraint use. For the NCSS file, many variables are associated with a much higher fatality rate. Of these, accident level variables include number of vehicles involved, urbanization, and fire or explosion incidence. High fatality vehicle variables include the change of velocity at impact, the direction of impacting force, and vehicle damage area. Occupant variables include seating position, age, sex, ejection, entrapment, and restraint use. Rollover and ejection are each independently associated with a higher fatality rate, with ejection appearing to be more significant. NCSS is considered the best currently available source of accident data for analyzing injury-related factors.

SPECIAL ADJUDICATION FOR ENFORCEMENT (SAFE) SEATTLE. FINAL REPORT SUPPLEMENT

This supplemental evaluation examined the impact of the excep
tions made to predesignated treatment assignment, and assesse
the relative effectiveness of each version of the course. Th
effectiveness of three versions of the Defensive Driving Cours
was evaluated within the context of referral to treatment fro
the Special Adjudication For Enforcement system. The impac
of the exceptions was minor. A few differences in group compo
sition were found, but multiple regression analytic technique
controlled for the potentially biasing effects of these variables i
the recidivism analyses. Modest but significant reductions i
citation recidivism were detected for the Driver Improveme
Program (DIP) version of the course, probably the most prom
ising for future programs. The cost-benefit potential of the pr
grammed learning version of the course should be considere
as the instructor costs of DIP per student are substantiall
higher. Further exploration and evaluation of the Defensiv
Driving Course is recommended.

INCREASED D.U.I. (DRIVING UNDER THE INFLUENCE) ENFORCEMENT PROGRAM, STOCKTON, CALIFORNIA. ANNUAL REPORT (3RD)

A compilation and evaluation is presented of data relating to th
1977 enforcement and roadside survey activities of the Stockto
Increased Driving Under the Influence (D.U.I.) Enforceme
Program. The project applies increased levels of personn
toward the reduction of alcohol-related accidents through d
tection and apprehension of persons driving under the influen
of intoxicants. The evaluation design called for an initial thre
month period of zero enforcement followed by nine months
enforcement with ten officers working city wide. After the Ta
Force was reinstated during the second year, alcohol and no
alcohol related collisions were lower than baseline levels, b
the change was not statistically significant. The roadside surve
measuring blood alcohol content indicated a reduction in t
number of persons drinking during Experimental Hours, partic
larly from 2 to 4 a.m. Traffic Task Force activity data sho
that the Task Force did impact the drinking driver; analysis
the collision data by areas of patrol concentration shows d
creases in total collisions in the area where Traffic Task For
activity was greatest and increase in collisions where it w
minimal. The results suggest that the original statistical desi
was not sensitive to changes in the collision data. Enforceme
recommendations are made for the future.

AN ANALYSIS OF THE IMPACT OF DRIVER EDUCATION ON THE LICENSING OF 16 AND 17 YEAR OLDS

Multiple regression analyses were used to estimate the strength of the relationship among driver education enrollment, the presence of laws requiring driver education for licensing before age 18, and the rate of licensing of 16- and 17-year-olds between 1965 and 1975. Results showed that driver education is significantly and positively related to the licensing rate of 16- and 17-year olds. This relationship may be as strong as a .42 increase in licensed drivers per enrollment in driver education. The relationship was not greatly diminished when economic and mobility factors were controlled, and was stronger between 1971 and 1975 than it was between 1965 and 1970. The presence of driver education laws had a significant direct negative relationship with the licensing of young drivers while it had a positive relationship with driver education enrollment. These results suggest that driver education probably accounts for at least some increase in the licensing of young drivers. The implications of these findings for high school driver education, motorcycle rider education, and education for traffic offenders are discussed. Appended are a review of states with and without driver education provisions for driver licensing and plots of driver education and licensing data by state.

THE NATIONAL ACCIDENT SAMPLING SYSTEM; A STATUS REPORT. VOL. 4: IMPLEMENTATION SCHEDULE AND RESOURCE REQUIREMENTS

When the complete National Accident Sampling System (NASS) is in operation, approximately 18,000 accidents will be selected annually by a carefully designed sample, and data will be gathered by accident investigation teams. The data will be used to design and evaluate highway safety measures. Detailed implementation planning by the National Center for Statistics and Analysis in support of NASS is described. The following major implementation tasks have been identified: implement a pilot Continuous Sampling System, design special studies, design improved sample frame, develop accident causation methodology, develop exposure data system, evolve regular field operations, combine exposure and pre-crash data analysis, revise field data collection and quality control, expand to a national system, develop analysis for NASS estimates, and operate an integrated national system. Resource requirements (manpower and funding) are also discussed.

AN EVALUATION OF STANDARD 214 (SIDE DOOR STRENGTH OF PASSENGER CARS)

A preliminary evaluation was undertaken to determine the effectiveness of Federal Motor Vehicle Safety Standard (FMVSS) 214 in preventing intrusion and occupant casualties in side impacts, to measure the actual cost of the standard, and to assess its cost effectiveness. FMVSS 214 sets crush resistance requirements for the side doors of passenger cars. The evaluation was based on statistical analyses of National Crash Severity Study accident data and teardown analyses for cost estimation. It was found that FMVSS 214 prevents a substantial proportion of fatalities and severe injuries in single-vehicle, side-door impact crashes. The standard reduces the likelihood of intrusion in nonlateral, side-door impact crashes. It is significantly less effective in multi-vehicle crashes. FMVSS 214 adds $56 to the cost of purchasing and operating a car over its lifetime. It was demonstrated that the performance requirements of the standard are meeting their goal of reducing intrusion in side-door impacts, and that the standard is cost-effective. Additional calculations, raw data, effectiveness evaluation tools, trends, and effects relating to the promulgation or non-promulgation FMVSS 214 and casualties are appended.

MOTOR VEHICLE SAFETY DEFECT RECALL CAMPAIGNS REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, APRIL 1, 1979 TO JUNE 30, 1979

Following a summary of tabulations of recall campaigns, details are given on the individual domestic and foreign recall campaigns, with information on NHTSA identification number, date of company notification, make and model, model year, number of pages on file, number of vehicles recalled, a brief description of the defect, and the manufacturer's corrective action. Status of the recall campaigns as of March 31 is provided. Types of vehicles recalled include passenger cars, motorhomes, station wagons, light, medium, and heavy duty trucks, camper vans, camper trailers, buses, school buses, and motorcycles. Equipment under recall includes tires, anti-lock brake systems, axles, jacks, fuel filters, steering column assembly components, luggage racks (on motorcycles), and fuel hoses.

THE NATIONAL ACCIDENT SAMPLING SYSTEM MEETING HELD OCTOBER 16-17, 1978

A public meeting was held on 16-17 Oct 1978 in Rosslyn, Va. to review the progress of the National Accident Sampling System (NASS) over the two years since the last review and to make recommendations to the National Hwy. Traffic Safety Administration (NHTSA) to enhance NASS implementation in the future. Twenty-three participants reviewed documents and presentations prepared by NHTSA and contractor staff. Following subcommittee deliberations, they unanimously agreed upon 22 recommendations which were submitted to NHTSA on 19 Dec 1978. Background information is presented on the objectives, organization, structure, and implementation of NASS, and the preparation and agenda are described. The recommendations concerning NASS implementation, operation, and policy, and response by NHTSA are presented. Appended are lists of participants and attendees. It was concluded that since the 1976 review, the NASS has made steady progress, and that most of the previously identified problems have been solved or are being addressed.

NATIONAL ACCIDENT SAMPLING SYSTEM. PILOT STUDY. FINAL REPORT

A pilot study of the National Accident Sampling System (NASS), using ten randomly selected data collection sites, demonstrated the feasibility of the concept as a means of producing a nationally representative accident data base. Overall missing data rates and nonresponse rates for major field tasks reached acceptably low levels by the end of the study. Urbanized areas had a missing data rate approximately twice as high as rural areas with respect to important NASS variables. The initially high error rates experienced by most data collection teams were improved through remedial training, and did not appear to be affected by locale. The error and missing data rates, and the variability of the latter were found to be sensitive indicators of training deficiencies, coding procedure ambiguities, and weaknesses in data definition. A smaller team size of three persons proved adequate to the investigative tasks. In urban centers, a larger team may have less difficulty in keeping the missing data rate at an acceptable level. Uniformity of the nonquantifiable aspects of quality control of the NASS data file that depend upon subjective judgment can be achieved only through intensive, centralized management oversight.

CORPORATE STRATEGIES OF AUTOMOTIVE MANUFACTURERES. VOL. 1: AN EXECUTIVE SUMMARY. FINAL REPORT

Results are summarized of a study to describe and assess the corporate decisionmaking processes of major domestic automotive manufacturers: American Motors, Chrysler, Ford, and General Motors. Through a series of quantitative and judgmental models, the attractiveness was estimated of a number of alternative strategies for each manufacturer, with an assessment of the long-term impact of these strategies on financial and other characteristics of each firm. Technological strategies appear better responses for the financially stronger firms; lobbying and organizational strategies most important to weaker firms. It is concluded that all the domestic manufacturers will survive and meet the 1985 fuel-economy standards, that AMC will phase itself out of passenger automobiles in favor of its light-truck and bus business, and that Chrysler's market share will decrease in the face of increased competition from GM, Ford, and foreign manufacturers.

CORPORATE STRATEGIES OF AUTOMOTIVE MANUFACTURERS. VOL. 2: A COMPREHENSIVE SUMMARY OF LIKELY ACTIONS BY DOMESTIC COMPANIES UNDER FUEL-ECONOMY REGULATIONS: 1978-1985. FINAL REPORT

The likely actions and policies of the four major U.S. manufacturers (American Motors, Chrysler, Ford, and General Motors) between 1978 and 1985 are described. The socioeconomic scenario is a composite based on long-term forecasts of economic growth, excluding possible recessions or booms, consistent with secular forecasts of most major econometric data services. In descriptions of the various companies, an industrial dynamics model was used to project total demand for automobiles, and a model based on historical factor analysis of new-car purchases was used to simulate consumer response to the companies; the market shares of each company were projected. Another model estimated each company's strategies for meeting the fuel-economy standard. A financial analysis of the individual firms was then made, with projections of the financial indicators. Appended are an analysis of recurring issues affecting boardroom decisions and a study of time-lines in new-product development.

CORPORATE STRATEGIES OF AUTOMOTIVE MANUFACTURERS. VOL. 3: AN HISTORICAL PERSPECTIVE ON THE AUTOMOTIVE INDUSTRY. FINAL REPORT

An historic overview is presented of the corporate strategies of the four major automotive manufacturers: American Motors, Chrysler, Ford, and General Motors. The socioeconomic environment of the past 20 years is described, with each manufacturer's response to external influences, and its resulting financial and other characteristics. Changes in conditions in the U.S. which influenced the business strategies and product lines of the industry are discussed, including government regulations, labor relations, foreign competitors, availability of materials, and fluctuations in the economy.

CORPORATE STRATEGIES OF AUTOMOTIVE MANUFACTURERS. VOL. 4: ADAPTATION OF A COMPUTER SIMULATION MODEL OF THE INDUSTRY. FINAL REPORT

The adaptation of a computer simulation model is described and assessed for use in studying the corporate strategies of automotive manufacturers. The original model was developed by Pugh-Roberts Assoc. to assess the corporate strategies of automotive manufacturers in response to changing economic, regulation, and consumer buying patterns. Deficiencies in the original model have necessitated a number of changes; those already incorporated in the new version by The Futures Group have resulted in a reasonable fit between historical auto sales and the model's simulation of auto sales. Until the balance of recommended changes are made, the remaining outputs are not usable. A cost estimate to complete the changes is given.

ASSESSMENT OF VEHICLE SAFETY PROBLEMS FOR SPECIAL DRIVING POPULATIONS. FINAL REPORT

Vehicle safety problems are described which were reported in interviews with 460 physically limited drivers and 41 physically limited non-drivers. The problems involved operation of primary and secondary controls, operating other vehicle mechanisms (e.g., restraints, seat adjustments), seeing properly, getting in and out of the vehicle, and handling certain tasks outside the car. The following needs were identified: Better dissemination of information to physically limited drivers concerning vehicle design considerations, equipment options, available aids and devices, operating procedures, and procedures for maintaining adaptive control equipment; development of additional assistive devices, including a secondary control stalk, rear vision system, supportive restraint systems, and a means of preventing feet from sliding under foot pedals; improvements in adaptive control systems, including improvements in reliability, comfort, compactness, and physical appearance.

SCHOOL BUS PASSENGER SEAT AND LAP BELT SLED TESTS. FINAL REPORT

A sled test program was conducted for route school bus and activity bus occupant seats to determine the response of dummies in simulated frontal collisions, using the variables of seat spacing, test velocity, lap belts and no lap belts, differing dummy sizes, and seats from different manufacturers. Test results, with photographs, are presented, and an evaluation of the results is made. Lap belts do not seem to have a significant effect on the response characteristics of a 50th percentile adult male dummy, for the test conditions. Seat spacing has only a minor effect on the response characteristics of the adult dummy and only a slightly higher effect on the child dummy. The head response of the adult dummy seems to be dictated by the head/seat back contact geometry; impacts to the neck and throat offer the greatest protection from head accelerations. Impacts involving the child dummy show a severe spinal whipping apparently caused by the "beaming" of the torso inertial loads to the head and knee contact points; further study in this area is recommended. Impact speed affects the child dummy more than the adult. Compartmentalization seems to be a problem primarily for the larger dummy size; all child dummies were 100% contained during impact and rebound. Since all tests were normal (0 degree) frontal impacts, compartmentalization may be sensitive to the obliqueness or angle of impact, especially to the unbelted dummy.

1978 ANNUAL REPORT. TENNESSEE CHILD PASSENGER SAFETY PROGRAM. FINAL REPORT

During the year that the Tennessee law providing for protection of child passengers less than four years old has been in effect, the child Passenger Safety (CPS) program has been providing both a public information and education campaign to supplement the law, and an evaluation of the effectiveness of the promotional campaign. The 1978 activities of the CPS are described, including a discussion of the public information and education (PIandE) campaign, some measures of its effectiveness, and objectives for the coming year; previous relevant research is described; specific segments of the public information and education activities are considered; and data collection, analysis and interpretation are discussed. The PIandE plan is functioning well; child restraint device sales were substantially higher in 1978 than previously; community contacts and commitments increased. An educational campaign to raise the level of safety consciousness is recommended; certain child restraint device design problems related to comfort and convenience must be solved. Most important is strict enforcement of the law.

SUPPORT FOR ANALYTICAL TOOLS FOR AUTOMOTIVE FUEL ECONOMY ACTIVITIES. FINAL REPORT

Several tasks are described involving the development, implementation, and documentation of analytical tools and computer software in support of activities related to automotive fuel economy. These activities include documentation and modification of a fuel economy projection program, tabulation of percentage of automobile sales by weight class and model year, manipulation of files from the 1978 Environmental Protection Agency data base, determination and prediction of survival probability as a function of vehicle age (automobiles and trucks), and determination of the distribution of reported fuel economy errors due to rounding and the distribution of inertia weight error due to classification. Also included are an analysis of 1976-77 data concerning vehicle miles travelled on the basis of magnetic tapes received from the State of New York, and development and implementation of a data base management system that will facilitate enforcement of automobile dealer compliance with regulations requiring display and availability of fuel economy information for the consumer. Procedures used to maintain data base integrity and security are also documented.

AN ANALYSIS OF MOPEDS AS A POTENTIAL SAFETY PROBLEM IN THE UNITED STATES. VOL. 1: REVIEW OF THE LITERATURE AND DATA SEARCH. FINAL REPORT

A procedure was formulated to forecast the nature and scope of the moped accident problem potential in the U.S., to predict outcomes for such input values as sales volume, usage patterns, and crash rates, and based on the outputs, to recommend National Hwy. Traffic Safety Administration research and safety program action. Foreign literature sources are examined which describe the use of the moped in other countries and relate this to the U.S. experience. Topics include moped legislation abroad and in the U.S.; numbers of mopeds, extent of usage, and user characteristics; accident data (primarily rider and environment); collision characteristics; and the nature of injuries to accident-involved moped riders. In the U.S., the moped is used by many persons over 45 to 50 years of age, primarily for pleasure and recreation, while in Europe its use is more by the young for utilitarian purposes; this difference affects the accident experience. There is a move toward mandatory use of helmets in Europe. The appendix includes a review of the docket on motorized bicylces and findings from an independently conducted market survey on U.S. moped sales and characteristics of the users. Data are provided from interviews with executives of the six largest moped distributors in the U.S. for use as independent projections of future sales. The survey also uncovered several consumer characteristic surveys from which selected tabulated data are provided.

ADVANCED CRASH RECORDER DEVELOPMENT. IMPLEMENTATION PLAN

The implementation plan is presented for advanced crash
corder use in evaluating vehicle accident data. Major eleme
of the implementation plan encompassing acceleration data
associated accident parameters are acquisition (recorder depl

ment and data retrieval), consolidation (rapid access and crash data assimilation), and processing and analysis (data base development, data reduction, and studies and reports). The effective use of actual vehicle accident data can enhance the development, implementation, and evaluation of motor vehicle and highway safety standards and countermeasures. Successful implementation of the advanced crash recorder depends on recorder deployment and the retrieval of pertinent accident data at minimum cost. Acceleration data retrieval can be accomplished in conjunction with routine accident investigation tasks. Accident data can be quickly consolidated at the analysis center via commercial telephone circuits. The data retrieval and analysis system provides the capability for immediate processing and the development of a historical data bank. Benefits of this system include rapid association of accident parameters, immediate access to current accident information, reduced analysis time and costs, and early trend recognition.

MODEL 44400 AUTOMOTIVE CRASH RECORDER.

Engineering tests were performed on Teledyne Geotech's Model 44400 Automotive Crash Recorder, in order to prove basic design concepts and circuitry for five prototype units. Performance tests focused on requirements, clock frequency, memory battery current, calibration, trigger level, functional voltage level, linearity, primary power loss, and temperature drift. Environmental tests concerned high/low temperature, temperature/humidity, vibration at room high/low temperature, shock at room high/low temperature, and salt fog. Test results identified areas of needed improvement.

THE DESIGN, IMPLEMENTATION, AND OPERATION OF A MOBILE DIAGNOSTIC INSPECTION SYSTEM IN THE METROPOLITAN ST. LOUIS AREA. FINAL REPORT

Testing performed as part of the Mobile Vehicle Inspection/Repair Program is detailed. Program objectives are to eliminate inconvenience associated with vehicle diagnosis and repair, to conduct a thorough diagnosis so that only necessary repair work is performed, and to communicate the condition of the vehicle to the owner in accurate and understandable terms. Five projects implemented in the St. Louis area pertained to vehicle diagnostic inspection and repair for company employee vehicles on company parking lots, management of a company fleet, individual vehicle inspection and maintenance at the owner's residence or place of employment, working with oil company garage networks to increase station bay utilization and to reactivate neighborhood repair facilities, and service for vehicle leasing companies. Vehicle inspection, diagnostic, and repair procedures are described, and case results of vehicle inspections and repair work presented. Equipment cost and van layouts are shown, and system constraints are discussed. Suggestions regarding general system application on a nationwide basis are offered. Appended are vehicle inspection procedural information, specific case results, news articles, and forms used in mobile inspection and repair programs.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR STATE TRAFFIC RECORDS. FISCAL YEARS 1980-1984

The plan is designed to develop state traffic records systems that can provide information in a format easily summarized at the national, regional, state and local levels of government for program planning, management, and evaluation. Problems inhibiting the development of adequate data and data systems are addressed. In priority order, the aims are to improve the content and quality of accident data, to upgrade data analysis capability in each State, to demonstrate Model Traffic Records systems, to promote data uniformity and standards through the American National Standards Inst. D-20 process and the National Hwy. Traffic Safety Administration Design Manual, to maintain a management information system responsive to the needs of traffic safety program managers, and to establish improved position location systems for accidents, traffic citations, or roadway features. A discussion of current problems with traffic records systems (incompleteness, unreliability, lack of standardization) is followed by a review of projects giving support and technical guidance to traffic safety programs. Among these are the Data Analysis and Reporting Techniques (DART) project, the Model State Traffic Records System, and the LORAN-C (Long-Range Navigation) project, the last adapted from a marine navigation system. A sample six-year budget plan is included.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR MOTOR VEHICLE REGISTRATION, TITLING, AND ANTITHEFT. FISCAL YEARS 1980-1984

The program plan is designed to improve the effectiveness and uniformity of state registration and titling practices, to develop methods to deter motor vehicle theft, to identify vehicles and owners rapidly, to assist in prevention and recovery of stolen vehicles, and to encourage owner response to manufacturer defect recall campaigns. While the states' capability for rapid identification of vehicles and owners has increased in past years, the traditional concept of the vehicle registration program as a revenue producer has retarded its safety potential; the program should be regarded primarily as a support to highway safety. All states should have a title law, with effective ownership procedures requiring physical checking of the VIN, review of ownership documents, control of registration plates, and of salvage vehicles and their titles, to help prevent the fencing of stolen vehicles. Compliance with the defect recall campaigns should be promoted. A budget plan for motor vehicle registration, titling, and antitheft procedures for 1980 through 1984 is included.

CONSUMER RESOURCE GUIDE (FOR AUTOMOBILE INFORMATION AND AVENUES FOR COMPLAINT)

This consumer resource guide tells how to obtain information on automobiles and where to go with complaints. It includes a list of national consumer affairs associations, Federal agencies concerned with automobiles, manufacturers and their addresses, automobile-related publications, Federal Information Centers operated by the General Services Administration, and Action Line broadcasters. The focus is on government consumer offices and private consumer groups. A toll free telephone number (800-424-9393) is provided for an auto safety hotline, sponsored by the National Hwy. Traffic Safety Administration.

REMARKS BEFORE THE WESTERN CONFERENCE CONVENTION OF THE INTERNATIONAL BROTHERHOOD OF TEAMSTERS, SEATTLE, WASHINGTON, AUGUST 27, 1979 (TRUCKING SAFETY)

In 1978, only 27% of trucks surveyed by the National Hwy. Traffic Safety Administration (NHTSA) were travelling at or below 55 mph; over 32% were exceeding 60 mph. Fatalities involving combination trucks grew to over 4600 in 1978, an increase of 39% over 1975; 73% of these fatalities occurred on roads posted at 55 mph. Professional truck drivers should voluntarily comply with the 55 mph law, not only for safety but also for fuel economy reasons. One of the major priorities of NHTSA in 1979 is large truck safety. Ride quality is another major concern. In NHTSA's Five Year Plan for Motor Vehicle Safety Rulemaking (Apr 1979), items related to heavy-duty vehicles cover interior noise levels, rear underride, stopping distances, hazards of the explosive separation of multipiece rims, direct fields of view and mirror systems, and truck splash and spray. Bureau of Motor Carrier Safety rulemaking is also underway on cab interior temperatures, and on fumes and toxic gases. Participation is invited by Teamsters union representatives and individual truck drivers at an NHTSA public meeting on truck safety to be held in Washington, D.C. on 10-11 Sep 1979. NHTSA emphasizes the importance of the trucking industry in continuing to advise the agency on truck safety matters.

REMARKS BEFORE THE 1979 AUTOMOTIVE NEWS WORLD CONGRESS, DETROIT, MICHIGAN, JULY 25, 1979 (FUEL ECONOMY)

The automakers must play a major role in achieving U.S. lon
range fuel conservation goals. Average fuel economy levels i
the 40 to 50 mpg range projected for the 1990's would sav
about 2 million barrels of oil a day (the amount now bein
imported). The trend toward more fuel-efficient cars has no
been firmly established. Heavy industry investments in downsi
ing, the preponderant emphasis on fuel economy in automotiv
advertising, and the worldwide quest for a new energy-efficien
environmentally clean, and safe car all demonstrate a near tot
commitment to the socially responsible car. Motor vehic
safety developments must proceed in step with energy efficienc
developments. As an example of a safe and energy-efficient ca
the Minicars Research Safety Vehicle gets 30 miles to the gallo
and offers occupant protection in a 50 mph frontal barri
impact and in a side impact by a similar sized car at the sa
speed. If the U.S. auto fleet had the same characteristics, annu
fatalities could be reduced by over 12,000 and fuel usage b
half. Timely investments in innovative research and develo
ment can reduce automotive expenses and can make the U.
industry fully competitive with foreign automakers.

REMARKS BEFORE THE ALLIANCE OF AMERIC INSURERS, BOSTON, MASSACHUSETTS, MAY 21, 1979

Economic efficiency and health-safety aspects of the insura
industry are addressed. Achieving reductions in environme
and safety hazards is a difficult task. Some insurance executi
are reluctant to cooperate with government entities because
concern that support for regulatory activities will increase re
lation of the insurance industry itself. This view fails to dis
guish between health-safety regulation designed to protect
public from needless bodily harm and economic regulation,
it fails to recognize that health-safety regulation may red
public outcry to the high costs of insurance coverage.
insurance industry can take steps to minimize highway rela
losses. Possible options are to publicly report findings in
course of regular insurance investigations on harmful produ
and safety defects; to differentially rate cars based on de
characteristics; to use fleet purchases to influence prod
design; to encourage public communications; to influence pu
policymaking in Washington, D.C.; and to foster vehicle sa
design and production.

STATEMENT BEFORE THE SUBCOMMITTEE ON ENERGY REGULATION, SENATE COMMITTEE ON ENERGY AND NATURAL RESOURCES, CONCERNING S. 1337, A BILL TO PROVIDE GREATER COMPLIANCE WITH THE NATIONAL MAXIMUM SPEED LIMIT, SEPTEMBER 17, 1979

It is proposed to increase the severity of sanction procedures established by 1978 amendments to the national maximum speed limit, by increasing the percentage of a State's motorists that must conform to the 55-mph speed limit each year, and by increasing the amount of noninterstate funds withheld if a state fails to meet the required compliance percentage. Since the 55-mph speed limit was introduced in Jan 1974, a dramatic reduction in highway deaths and injuries has occurred, from 54,052 in 1973 to 45,196 in 1974. It is estimated that at least half of the lives saved are directly attributable to slower and more uniform traffic flow produced by the national speed limit. Medical studies indicate that the number of spinal cord injuries caused by automobile accidents has dropped significantly and that the most important factor in injury reduction is the reduced speed limit. Enforcement of the 55-mph speed limit is the responsibility of States. Individual law enforcement agencies are engaged in innovative and aggressive enforcement programs, and several states use aircraft in speed limit enforcement. National speed limit activities are examined, public support of the limit is reported, and speed monitoring is discussed.

REFRESHER TRAINING PROGRAM FOR THE BASIC EMERGENCY MEDICAL TECHNICIAN. COURSE GUIDE.

This course guide describes a refresher training program for emergency medical technicians (EMT's) which is designed to assure continuance of a uniformly high level of knowledge and skills among EMT's who have completed the Dept. of Transportation's Basic Training Course. An introduction, including a course overview, is followed by sections on course administration, resource requirements, and course evaluation procedures. Appended are a sample application packet, handout materials, a refresher training program resources table, and a process evaluation checklist. The course is to be offered under the medical direction of a physician and a Course Administrator. The administrator should be experienced in emergency medical care, should be aware of the legal constraints under which EMT's operate, and should work closely with the medical director to assure constant course updating. He should also know the performance requirements of experienced EMT's in the jurisdiction where the course is offered. The course is divided into 20 lessons, each of which requires 1 to 1.5 hours to complete. The lessons may be given in individual units for presentation one or more times a week, may be combined into 6- to 8-hour units for presentation in a 3 to 5-day period, or may be offered over an extended period ("continuing education"). The majority of lessons will be presented in a classroom, with sufficient space for seating a maximum of 20 students, and a lecture and demonstration area. It is recommended that this facility be located at a hospital. Since one lesson requires the use of automobiles, a special facility such as a garage or school is required. Two separate but interdependent types of evaluation are required. Process evaluation is used to determine if the training personnel are performing as planned and that the program schedule is being maintained. Outcome evaluation pertains to trainees' achievement of satisfactory job performance knowledge and skills.

TRAINING PROGRAM FOR OPERATION OF EMERGENCY VEHICLES. PURSUIT DRIVING FOR LAW ENFORCEMENT OFFICERS. ADVANCED UNIT

Administrative considerations, the Pursuit Driving Course Unit, instructor preparation activities, trainee knowledge and performance objectives, and individual course modules are described for the emergency vehicle operation (EVO) training program, which is designed as a practical, in-vehicle course. Trainees qualified to take this unit have completed the basic EVO Curriculum (Parts 1, 2, and 3). They should be authorized representatives of a law enforcement agency. Pursuit Driving instructors must be experienced and skilled in high-speed driving techniques. The class size should not exceed 12 trainees, and an instructor/trainee ratio 1:3 is most desirable. Facilities required include classroom(s), a skid pan, an oval track, a "high-speed" track, intersection area, and a vechicle maintenance area. The following types of vehicles are required: vehicles for high speed and oval track (with rollbars, reinforcements, and extra restraints), vehicles with "racing slicks" for skid pan use, emergency standby and "civilian" vehicles, and a large fire truck. Two 90-minute films pertaining to high-speed pursuit driving (or one film and Commentary Driving exercises) are required. Assuming the functional requirements are satisfied, the Pursuit Course requires two days. The course contains six modules, geared toward developing trainee skill in high-speed pursuit driving. Trainees will have an opportunity to practice and demonstrate their abilities on the skid pan, oval track, and high-speed track.

Highway Safety Literature

U.S. Department of Transportation National Highway Traffic Safety Administration

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safety Administration (NHTSA). It is divided into the following sections: Abstract Citations, containing bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-of-context (KWOC) list of words in the title, followed by the full title and HS number (our accession number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Report Number Index. In those months when information on contracts recently awarded is available, a section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technical Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Editor at the address below for inclusion in the collection and abstracting in this publication. Please indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for information. Views expressed are those of the authors and not necessarily those of the Administration. Reference to brand names, equipment, models or companies does not imply endorsement by NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Safety Literature** may be addressed to

National Highway Traffic Safety Administration
400 7th St. SW
Washington, D.C. 20590

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive Engineers, Dept. HSL, 400 Commonwealth Drive, Warrendale, Pa. 15096. Order by title and SAE report number.

TRB: Transportation Research Board, National Academy of Sciences, 2101 Constitution Ave., N.W., Washington, D.C. 20418.

Corporate author: Inquiries should be addressed to the organization listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED BY MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning the maximum amount of brake pedal force that automobile drivers were able to sustain over a period of ten seconds. Subjects were told to apply the brakes in the test car as they would in a panic stop, and to exert as much force as possible on the pedal over the entire ten second test period. A total of 84 subjects were tested, including 42 males and 42 females. The results indicated that there is a wide distribution of values which characterizes the pedal force that the subjects were able to generate. Male subjects produced generally higher forces than did females. Over half the women tested were unable to exert more than 150 lbs. of force with either foot alone, but when both feet were applied to the pedal, force levels rose significantly.

NHTSA accession number	HS-018 924
Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflation pressure are deduced by assuming the bias tire as a composite structure of a bias-laminated, toroidal membrane shell and rigorously taking three displacement components into consideration. The point collocation method is used to solve a derived system of differential equations with variable coefficients. It is found that the lowest natural frequencies calculated for two kinds of bias tire agree well with the corresponding experimental results in a wide range of inflation pressures. Results of the approximate analysis show that the influences of the in-plane inertia forces on natural frequency may be considered small, but the influences of in-plane displacements are large, particularly on the natural frequency of the tire under low inflation pressure.

SERVICE AND METHODS DEMONSTRATION PROGRAM. ANNUAL REPORT. EXECUTIVE SUMMARY (URBAN MASS TRANSPORTATION ADMINISTRATION)

Activities and accomplishments of the Urban Mass Transportation Administration Service and Methods Demonstration (SMD) Prog. during fiscal year 1978 are summarized, with emphasis on the relevant findings of the innovative service and methods concepts being tested, the gaps that still exist in understanding their effectiveness, and the direction of future efforts to fill these gaps. Project activities are organized into four major program areas: conventional transit service innovations (priority techniques for high occupancy vehicles, traffic restrictions, transit service improvements, and vehicle innovations), pricing and service innovations (fare payment strategies, fare-free transit, road and parking pricing, pricing and service variations), paratransit (demand-responsive transit, transportation brokerage, ridesharing, and subscription bus), and service for special user groups (elderly and handicapped persons, persons with limited income). Services for special user groups include specialized demand-responsive transportation, user-side subsidies, social service agency transportation, and accessible fixed-route bus services. Support activities in the areas of evaluation methodology and information dissemination are also described. The SMD Prog. focuses on strategies which require relatively low levels of capital investment and which can be implemented in a short time frame.

ALCOHOL AND TRAFFIC SAFETY: A SELECT ANNOTATED BIBLIOGRAPHY

Bibliographic information and abstracts are provided for 89 journal articles and conference papers on the subject of alcohol and traffic safety. Topics covered include rehabilitation and education programs; social, demographic, and psychological characteristics of persons cited for driving while intoxicated; experimental studies; traffic accident records; accident fatalities (including motorcyclists and pedestrians); recidivism; enforcement and adjudication; public information campaigns; traffic safety education; legal drinking age; young drivers; alcohol and other drugs; the role of the physician; licensing controls; and determination of blood alcohol concentration.

THE IMPORTANCE OF LANE-CHANGING ON MOTORWAYS

Measurements were taken on the Bundesautobahn A5 between Bruchsal and Karlsruhe in Germany to investigate vehicle lane changing, passing, and overtaking. As traffic volume increased, it was found that the lane-changing frequency strongly increased at first, and then increased less than proportionately until it attained a maximum value of 600 lane changes/hr.km at a traffic volume of 2000 vehicles/hr. At higher traffic volumes, lane-changing frequency was reduced. With growing traffic volume, the demand for lane changing increases; but the opportunities to pass decrease. The maximum value of, on average, 3500 passings/hr.km was found to occur at a traffic volume of 2400 vehicles/hr. Higher traffic volumes resulted in reduced passing frequency, the result of the reduced speed difference between off- and near-side lanes. For a traffic volume of 2000 vehicles/hr, it was calculated that 10 vehicles are overtaken per overtaking (vs. passing) process. According to the observations, it can be expected that 10 to 15 obstructing lane changings/hr can be expected at traffic volumes exceeding 2000 vehicles/hr.km. Results of the study indicate that the possibility for lane changing on multi-lane highways relates to the overtaking possibility on two-way roads. When evaluating the accident rate corresponding to traffic volume, the conflicts arising from lane changings and their frequency should be taken into account. The introduction of a variable-message sign indicating NO LANE CHANGING should be considered, especially on the grounds of improved traffic safety.

THE ELECTRONIC GAS WATCHDOG. A UNIT SUITABLE FOR DETECTING THE PRESENCE OF GAS IN A SIGNAL CONTROLLER

An "Electronic Gas Watchdog" is being used experimentally in the West Midlands (England) County Council Traffic Control Areas, to warn of the presence of gas in traffic signal controllers. In the control areas (Wolverhampton and Conventry), part of the routine inspection of signals includes use of standard commercial "sniffers" to make two checks a year in low-risk areas and monthly checks in high-risk areas. Even with monthly inspection, detecting a gas leak before it reaches explosion concentration is a matter of luck. The recently available Electronic Gas Sensor is capable of detecting natural gas at a concentration well below that required for an explosion. In urban traffic control areas, electronic monitoring is particularly suitable, as the reply from the outstation transmission unit (OTU) to the control center normally has at least one bit not used for conventional reply data. The transmission of a gas alarm therefore requires only the connection of a suitable Gas Watchdog to the OTU, together with modifications to the control center software. Results of the first six weeks of the pilot experiment have been satisfactory. Since the long-term stability of the sensor unit is not known, it is being carefully monitored.

ENGINEERING THE '80S (AUTOMOTIVE DESIGNS TO MEET FEDERAL STANDARDS)

Engineering changes in 1980 model year cars to meet Federal emission and fuel economy standards are described individually for American Motors, Chrysler, Ford, and General Motors (Buick, Cadillac, Chevrolet, Oldsmobile, and Pontiac divisions). The technology used to meet the changes in emission standards to .41 g/mi hydrocarbons from 1.5 g/mi, 7 g/mi carbon monoxide from 15 g/mi, and 2 g/mi nitrogen oxides (unchanged), and stricter standards for California includes varying types of catalytic converters, air injection systems, feedback carburetors, and fuel injection. The first of four approaches used to achieve the 20 mpg corporate average fuel economy standard was improving driveline efficiency, notably through the use of lockup torque converters and new wide gear ratio transmissions (some with overdrive) and lower (numerically) rear axle ratios. Finer engine calibration has been made possible by electronic controls, feedback carburetors, and fuel injection systems. In order to reduce power requirements, aerodynamics continue to be refined to lessen drag, and rolling resistance has been decreased through the use of P-metric radial tires that can carry as much as 35 psi. Tread compounds are also being studied for additional reductions in rolling resistance. For reducing performance levels, engines are downsized with power to go from zero to 60 mph in 15 sec. Car weight was reduced by some use of alternate materials and by downsizing.

WILL DOWNSIZING DOWNSIZE YOUR PROFITS? (AUTO REPAIR INDUSTRY)

Most experts on the aftermarket believe that the downsizing of American automobiles will have little effect on profits of service shops. The theory is that opposing forces at work will have the net effect that smaller cars will neither increase nor decrease profits. While the new cars are more durable and will require less frequent replacement of parts, parts on small cars wear out faster than parts on big, heavy cars because they have to work harder to cover a given distance. Three other factors unrelated to car downsizing that will increase service business include: continuing growth of the car population, continuing increase in the number of miles driven by car owners each year, and increase in the length of time people are keeping their cars. The automakers have continuing programs to reduce parts numbers and to make more parts interchangeable between cars in the same family. General Motors is making more pieces standard between different car lines; the same rule applies to service tools. Independent shops and car dealers buy parts from many sources, and the number of parts manufactured and marketed by non-Detroit firms is increasing. The burden will not be on the installer of the parts, but on the wholesaler, who will have to maintain the stocks to service the cars. Another important factor is that the real profit for the auto mechanic is in labor, not in parts.

THE TROUBLE WITH AUTO WARRANTIES

All new cars made by General Motors, Ford, and Chrysler come with a basic, no-charge 12-mo/12,000-mi "limited" warranty. American Motors offers a "full" warranty called the "Buyer Protection Plan" which compensates consumers for the expenses of alternative transportation during repair work. The AMC plan avoids a major provision in the Magnuson-Moss Warranty Act, i.e. the "lemon provision" which offers a refund or replacement to the buyer for a product that is not repaired properly after a "reasonable" number of tries. The House Consumer Protection Subcom. has been holding hearings on a bill that would require automakers to offer a full warranty ("full" refers to consumers rights), if they give any warranty at all. Manufacturer's written warranties, TV commercials, brochures, and oral promises are all forms of "express" warranties which can be used to back up a consumer claim. An entirely different type of warranty, created by state laws under the Uniform Commericial Code, is called an "implied" warranty (the product has to be usable for the purposes for which it is intended). About 25 states have some provision for implied warranty protection beyond the express warranty period. In the last year, automakers have been promoting the "extended service contract". At a cost ranging from $75 to $365, these contracts protect against certain major repair expenses for 2 yr/24,000 mi to 5 yr/50,000 mi. Independent companies also offer this type of contract. It is important not to pay for coverage of repairs already included under the original, implied, or "secret" warranty. For the extended service contracts, the odds appear heavily weighted against the buyer. The so-called "secret" warranty covers defects that are widespread for a certain car model, but which appear after the 12,000-mi warranty expires. In separate sections, Canada's rust protection warranties are compared with those of the U.S., and extended service contracts are compared in a tabulation.

FUEL FOOD. A GAS-TRONOMIC GUIDE TO OCTANE IMPROVERS

In view of decreasing fuel octane ratings at the pump, some practical and effective ways of obtaining higher octanes for performance engines are explored. One approach is to dilute a good racing gasoline with straight pump fuel (only for use with engines which run on leaded fuel). With a 2:1 premium gasoline/racing gasoline mix, octane rating will go up 2.6 points. Top grade racing gasoline, with its high lead content, is limited to the race track. For engines which run only on unleaded fuel, a solution is a mixture of gasoline and alcohol ("gasohol"). A blend of gasoline with 10% methanol, for example, can raise the octane by 3 1/4 points. Based on methanol costing 75 cents/gal more than gasoline, this mixture will cost 2.5 cents/octane number/gal over the basic fuel cost (one-fifth the price of increasing the octane by using racing gasoline). Problems with methanol relate to the air-fuel ratio (rejetting may be required), fuel phase separation with water contamination, fuel system corrosion, and vapor lock at high temperatures. Ethanol offers similar results without as many problems, but costs 5 cents/octane/gal. One of the easiest ways for hot rodders to boost octane is to use commercial additives (mostly aniline); they can be used with all types of gasoline. At most, the cost per octane/gal of an additive is between 8.5 to 14 cents. A different approach is the use of water injection or carburetion system, offering the advantage of suppressing detonation only when it is about to happen. A water injection unit may cost $80 to $90, and requires careful calibration to meet specific engine needs, and addition of alcohol to prevent freezing.

USER GUIDELINES FOR REDUCED VISIBILITY SYSTEM DESIGN

This set of guidelines enables the user to determine the need for a reduced visibility guidance (RVG) system (for aiding motorists in such conditions as fog, dust, or blowing snow), to compare the needs of different locations on a quantitative basis, to configure candidate systems tailored to meet the requirements of the problem, and to compare the utility and costs of the candidate systems. The entire process is based on the results of an extensive survey and evaluation of the effectiveness of reduced visibility guidance systems. The evaluation was designed to determine which instruments, installation techniques, and operational measures were effective in dealing with reduced visibility, and the conditions in which they were effective. The survey was intended to obtain information, if possible, from every operational system in the continental U.S., and to discover the reasons why some systems have become nonoperational. The guidelines contain useful information on configuring systems, locating sensing and signing equipment, selecting among communications techniques and, if necessary, data processing techniques. Wherever equipment choices are to be made, each equipment type is described and its advantages and disadvantages are discussed, and a recommendation is made for reduced visibility applications.

THE BIG SHORTFALL IN AUTO FUEL ECONOMY

The Dept. of Energy (DOE) now estimates that by 1985 the cumulative shortfall between the Environmental Protection Agency (EPA) fuel economy ratings and the number of mpg actually obtained on the road may be the equivalent of 1 million barrels of oil/day or more. The fleet average rating of 27.5 mpg which automakers are required by law to achieve by 1985 may be less than 22 mpg in real-world terms. DOE, General Motors, and Ford Motor Co. studies of 1978 models indicated that the potential fuel economy has been overstated by 20% to 28%. EPA and Dept. of Transportation (DOT) officials say that the addition of only 22 engineers and analysts would double the size of the fuel economy program staff, allowing more confirmatory testing by EPA of prototype vehicles and the staffing of a strong analytical effort that might alleviate the shortfall problem. Half or more of the shortfall occurs because of the way the Energy Policy and Conservation Act was written. Certain fixed assumptions of unrealistic driving conditions and habits were locked into the program. According to EPA, the rest of the shortfall, estimated by DOE at one-third to one-half of the total, is the result of differences in fuel economy achieved by "hand-built" prototypes and production cars, and differences in vehicle performance on a dynamometer and on the road. Manufacturers are found to take advantage of loopholes in the fuel economy test procedures. In the review of fiscal 1981 budget requests, the Office of Management and Budget foresees questions concerning the adequacy of the EPA and DOT commitment to the fuel economy program.

CHARACTERISTICS OF BICYCLE-RELATED, MOTOR VEHICLE ACCIDENTS IN KENTUCKY

Data were obtained and analyzed for all bicycle-related, motor vehicle accidents which occurred in Kentucky between 1 Jul 1975 and 30 Jun 1976. Also analyzed were data on all injury-producing bicycle accidents recorded by the Kentucky Electronic Surveillance System in 1976. The 10- to 14-year-old age group had the largest number of bicycle-related, motor vehicle accidents, and the highest accident frequency. Males were involved in four times as many accidents as females. Accident severity tended to decrease as age increased. The highest proportion of accidents occurred between 3:00 PM and 7:00 PM. Most accidents occurred in urban areas, on residential streets. The most common type of accident was the right-angle accident and the most common accident involved a cyclist failing to stop or yield at a controlled intersection. For bicyclists 5 years of age or younger, most accidents resulted from the cyclist exiting from a driveway into the motorist's path. For those 20 years of age or older, the most common accident type involved a motorist colliding with the rear of a bicycle. Although the majority of accidents (71%) were the result of an error by the cyclist, the percentage of cyclists at fault decreased with increasing age. Bicycle-related, motor vehicle accidents represented under 10% of all injury-producing bicycle accidents.

THE EFFECTIVENESS OF REDUCED VISIBILITY GUIDANCE TECHNIQUES. STUDY. VOL. 1. FINAL REPORT

Effectiveness is evaluated in a detailed description of reduced visibility guidance (RVG) systems for aiding motorists in conditions such as fog, dust, or blowing snow, along with operating strategies. The evaluation is intended to determine which factors of system design contribute to system effectiveness and which approach is economically feasible for a specific highway condition. Literature, equipment, and operation system surveys were conducted. Data were assembled and analyzed from facilities which have RVG systems (located in Arizona, California, New Jersey, Oregon, Pennsylvania, Virginia and Wyoming). A utility/cost model was generated which permits quantitative comparisons between systems and "measure of need" index was devised to compare the seriousness of the hazard among different locations. The study resulted in a methodology which quantifies a reduced visibility problem and allocates resources systematically in proportion to the need. Appended are a literature review (including abstracts of primary references and keyword index); typical data requirements for system evaluation; special features evaluation studies; evaluation rationale for assigning utility model compliances in economic evaluation; sample system evaluation dockets; a discussion of the relationship between problem area characteristics and system elements; and estimated costs for nine model systems.

EVALUATION OF TECHNIQUES FOR WARNING OF SLOW-MOVING VEHICLES AHEAD. FINAL REPORT

An experiment was conducted at the Federal Hwy. Administration's Maine Facility to examine the relative effectiveness of roadside signs and vehicle markings for warning motorists of the presence of a slow-moving vehicle on a rural, two-lane road. A staged slow-moving vehicle was introduced into the traffic stream, and data were recorded on the reactions of overtaking motorists. Samples of motorists were exposed to different combinations of roadside signs, vehicle markings, and types of slow-moving vehicles. The use of standard four-way flashers was found to be an effective device for decreasing the potential of a dangerous conflict when a faster moving vehicle is overtaking a slower vehicle on an upgrade. Specific positive effects were relative to the initial reaction distance, closing rate, and minimum following headway. While the effects of the roadside signs were positive in the vicinity of the sign placement (out of sight of the slow vehicle), there were no lasting effects relative to the actual overtaking maneuver.

ASSESSMENT OF TECHNIQUES FOR COST-EFFECTIVENESS OF HIGHWAY ACCIDENT COUNTERMEASURES. FINAL REPORT

Improved cost-effectiveness techniques are developed for evaluating highway safety programs. These improved techniques include better methods of determining accident costs; statistical procedures for calculating accident costs; a consistent system for evaluating accident cost and countermeasure effectiveness; and improved incremental cost-benefit algorithm for ranking safety projects. A review of selected accident countermeasure studies and a critique of current procedures for evaluating safety programs are presented. Three techniques are recommended for use in allocating safety funds: incremental cost-benefit with improved algorithm; dynamic programming; and integer programming. Federal, state, and local highway safety activities are examined.

DEVELOPMENT AND VALIDATION OF ENGINE MODELS VIA AUTOMATED DYNAMOMETER TESTS

An automated engine dynamometer test procedure was developed and mathematical models for primary engine control variables derived from the resulting data base. Main engine variables were characterizations of fuel and emission flow rates as a function of air-fuel ratio, spark timing, percentage of exhaust gas recirculation, and any other required engine parameter for different engine speed and load operating conditions. The mathematical procedure involved sequential testing at many speed-load conditions for various combinations of air fuel ratio, spark timing and exhaust gas recirculation. Total testing time required to generate the data base of more than 2,000 test points was less than 12 hours. An independent transient speed-load test to validate engine models was conducted. Measured and model-predicted data were compared for this test which corresponded to one segment of the Environmental Protection Agency urban schedule. The inclusion of temperature as an independent variable in the emission modeling effort improved model quality, indicating that temperature is a factor in bridging the gap between steady-state and transient engine data. Information on regression analysis and modeling results is appended.

SPARK IGNITION ENGINE FUEL ECONOMY CONTROL OPTIMIZATION--TECHNIQUES AND PROCEDURES

Spark ignition engine control parameters (spark advance, air-to-fuel ratio, and exhaust gas recirculation) are analyzed in terms of optimum fuel economy, constrained emission levels, and tradeoffs. Emphasis is placed on procedures and techniques adopted for the off-line approach using steady-state mapping dynamometer data of conventional production engines. Analysis tools include vehicle simulation programs, Federal Test Procedure urban and highway drive cycle schedules, multiple regression techniques, and dynamic programming procedures. Applications of engine control parameter optimizations are illustrated, with reference to engine data bases (four-cylinder and eight-cylinder engines). Results are presented on fuel economy as a function of various regulated emissions and engine settings, and on increases or decreases in fuel economy relative to emission constraints, emission control strategy, and vehicle drive cycles. Hydrocarbon, carbon monoxide, and nitrogen oxide emission data are provided.

MACHINING STUDIES OF PM (POWDER METAL)-FORGED MATERIALS

Three typical powder metal-forged steels made from Hoganas powders have been studied with regard to their machining behavior using a special machinability test developed in 1960 by Volvo AB in Sweden. The test rates steels against a standardized free-machining steel, allowing recommendations for cutting data for turning, milling, drilling, tapping, and reaming of powder metal-forged materials to be empirically established. It is concluded that the powder metal-forged materials machine notably better than a common tough-hardening steel; two materials are as good as a common constructional steel and one material is better. Measured cutting and machine parameters for powder metal-forged materials are more consistent than those for comparable wrought steels.

THE DELCO REMY 5MT CRANKING MOTOR

The Innovative Delco Remy 5MT Cranking Motor is traced from project initiation in 1972 to its present production (begun in late 1976). The 5MT is a radical departure from its predecessor as the heart of the new 5MT motor is a powdered metal inner frame having the poles integral with the flux carrying frame. The manufacture of the powdered metal inner frame marks Delco-Remy's first powder metal fabricating venture. Only very minor problems were experienced in the start-up phase and based on limited production experience, no serious scrap problems have been observed. Tool wear has not been a problem, as the development data predicted (tool life estimated at 500,000 - 1,000,000 parts) and density does not seem to be a major factor in tool life. The success of the inner frame program has prompted expansion. The current projected potential of powder usage is 50,000,000 lb/yr in the next five years.

BLADE TYPE FUSES FOR ELECTRICAL CIRCUIT PROTECTION (AUTOMOTIVE APPLICATIONS)

A new blade fuse developed for low voltage (32 volts or less) automotive applications is discussed in terms of state-of-the-art advancement, under the following major topics: basic facts relative to fusing; review of existing performance standards for fuses in automotive electrical circuits; comparison of cartridge and blade fuse performance; reasons for the blade fuse's higher performance levels; and advantages in using the blade fuse in automotive circuits. The blade fuse was designed to fulfill the needs of the automotive industry for improved performance and reliability in a more space-efficient size. Achievement of this objective was the direct result of a design with fewer discrete components, reducing the chance for variability, coupled with a highly automated manufacturing process which maintains a high degree of production uniformity. The new fuse provides safer, less expensive, more trouble-free circuit protection.

SAFETY ASPECTS OF CURB PARKING. FINAL TECHNICAL REPORT

Relationships were examined among parking configurations (angle, parallel, or no parking), parking density, traffic flow, street width, pedestrian activity, and highway safety. A literature review identified 27 studies of accidents related to curb parking. (Abstracts of selected papers are appended.) Angle parking was identified in many studies as significantly more hazardous than parallel parking. Parking configuration variables associated with accident rates include functional classification of streets, utilization of parking spaces, and abutting land use. Data on over 4800 accidents associated with parking on over 170 miles of streets in 10 U.S. cities were collected and analyzed. Intersection and midblock accident comparisons were made for selected cities, and midblock accident rates were computed for the previously mentioned variables. No relationship was found between accident rate and street width or parking angle, but the rate was found to vary with land use (a surrogate variable for parking turnover) and parking utilization. Parking prohibition was estimated to reduce midblock accident rates from 19% to 75%, which is equivalent to total on-street accident rate reductions (including intersections) of 8% to 30%. Results of field studies suggest that speeds of, and delays to through vehicles are related to parking configuration. Speeds of through vehicles averaged 3.7 mph less when adjacent to angle parking, compared with parallel parking. Few pedestrian conflicts with curb parking were found. Backing sight distance restrictions caused by special vehicles (e.g. campers) had no effect on unparking times from angle parking lots. Sight distance for the backing driver was less for a 45 degree angle than for angles of 22 1/2 degrees or 30 degrees. The combined width needed for an adjacent lane plus parking lane was determined to be 22 ft for parallel, 26 ft for a 22 1/2 degree angle, 30 ft for a 45 degree angle, and 31 ft for angles of 60 degrees and over.

NATIONAL TRANSPORTATION STATISTICS. ANNUAL REPORT

Selected U.S. transportation statistics covering the period 1966 through 1976-1977 are provided in tabular and graphical form, as compiled from a wide variety of government and private sources. Included are cost, inventory, and performance data describing the passenger and cargo operations of the following modes: air carrier, general aviation, automobile, bus, truck, local transit, rail, water, oil pipeline, and gas pipeline. Basic descriptors of U.S. transportation are included, such as operating revenues and expenses, number of vehicles and employees, and vehicle and passenger miles. Formats used to spotlight aspects of the major transportation modes are tree displays, modal profiles, performance indicators, and transportation trends. Two supplemental data sections detail the role of transportation in the economy and the relation of energy to transportation. The first section provides time series transportation statistics for the period 1967-1977. The second section, covering the same period and extending back to 1950, is divided into four parts: energy consumption, energy transport, energy intensiveness, and energy supply and demand. Included are the operating costs of automobiles of different sizes. Appended are a bibliography, data sources for figures, tables, and profiles, and a glossary divided according to transportation modes.

COMPETITION DEVELOPS THE PRODUCT (DESIGN OF MOTORCYCLE TIRES, DUNLOP)

Dunlop's racing program is one method of intensive development of new motorcycle tire designs, enabling new technology to be passed on to the ordinary road user in a relatively short time. Dunlop's involvement in motorcycle racing competition began with the production of the first practical pneumatic (vs. solid) cycle tire. One of its first major contributions to road tire development was the "trigonic" profile (a tire cross section resembling a triangle with rounded corners) which allowed more of the sidewall to be utilized as tread area. As the power and performance of motorcycles increased, the trigonic profile became more rounded to accommodate straight-line high speed. Dunlop produced the first bias-belted tire, initially for racing and subsequently for the K91 road tire. In a bias-belted tire, the conventional cross-ply construction is supplemented by a textile (Kevlar aramid fiber) "breaker" placed under the tread. In order to provide a direct input to road tire development, technicians record every detail of performance at the race track; tire temperature provides important performance information. A prime requirement of design is a tire's ability to run continuously at motorcycle top speed; this ability is governed mainly by the speed at which a standing wave is generated behind the contact patch. The speed at which tread ripple sets in can be affected by numerous design factors associated with tradeoffs in other parameters, such as stability, handling, durability. It is hoped that the present emphasis on tread compounds will provide the average road user with the same benefits provided by recent work on profiles and tread patterns.

'79 REGULATORY SCENE IS RELATIVELY QUIET (AUTOMOTIVE INDUSTRY)

The Federal Trade Commission has ruled that automakers, starting with the 1979 model year, can advertise only city driving fuel economy figures appearing on the window sticker. "Highway" mpg figures can be used only for reporting Corporate Average Fuel Economy (CAFE) to Congress. Running contrary to the new labeling rule are CAFE standards that increase to 19 mpg in the 1979 models vs. 18 mpg in 1978. Passenger car emission standards are unchanged for 1979, but new standards for light-, medium-, and heavy-duty trucks become effective for the first time. Light trucks up to 8500 lbs gross vehicle weight (GVW) must meet 1.7 g/mi (grams per mile) hydrocarbons, 18 g/mi carbon monoxide, and 2.3 g/mi nitrogen oxides. Trucks over 8500 lb have three options based on g/bhp (grams-per-brake horsepower). Light trucks must also meet a maximum of 6 g/test evaporative shed emission standard. Although fuel economy of trucks will be measured and each vehicle labeled, trucks over 6000 lb will not be included in CAFE figures. For the 1979 models, automakers must certify that each vehicle is free of uncontrolled emissions that could be dangerous to public health. Automakers face a new laboratory procedure regarding dynamometer loading during new-vehicle emission certification. The first phase of new bumper damageability standards, replacing Federal Motor Vehicle Safety Standard (FMVSS) 215, Exterior Protection, is being introduced for 1979. FMVSS 212, Windshield Retention, coverage is being extended to all 1979 light-duty trucks up to 10,000 lb. A revised FMVSS 116, covering brake fluids, establishes a new color code and labeling requirements based on fluid grade.

AUTOMOBILE INSURANCE LOSSES, PERSONAL INJURY PROTECTION COVERAGES; CLAIM FREQUENCY RESULTS FOR 1977 AND 1978 MODELS

The frequencies of injury insurance claims to occupants of 1977 and 1978 model year passenger cars are presented by car size group, body style subgroup, and individual series. The results are derived from the "no-fault" personal injury protection injury experience of these car occupants from model introduction through Dec 1978. The data were supplied by four insurers: Aetna Life and Casualty, Allstate, Nationwide, and State Farm. Of the five high-volume (at least 1% of total exposure) 1978 models with the best and the five with the worst injury claim frequencies, the Oldsmobile Delta 88 four-door had the best record, the Honda Civic two-door the worst. All five 1978 models with the worst results were subcompacts (four imports by Datsun, Honda, and Toyota, and a domestic Ford product). All five 1978 models with best results were General Motors products (four intermediates, one compact; all four-door models). Three of the five 1978 models with the worst results (Honda Civic, Toyota Corolla, and Datsun B-210) were also among the 1977 high-volume models with the worst results. Four of the five 1978 models with the best claim frequency results (Oldsmobile Delta 88, Chevrolet Caprice, Buick LeSabre, and Chevrolet Impala) were also among the 1977 models with the best results. Cars with smaller wheel bases had much higher claim frequencies than cars with larger wheelbases. In each car size group, youthful operators had far higher claim frequencies than other operators. Regular two-door models had higher claim frequencies than corresponding four-door models. Within the subcompact, compact, and intermediate size groups, sports or specialty models had the highest claim frequencies.

SMALL IMPORTS DOMINATE 'WORST CAR' LIST

A news release announces the results of an analysis report by the Highway Loss Data Inst. (HLDI) of insurance injury claim frequencies for both 1977 and 1978 models from the time of their introduction through Dec 1978. For 1978 cars, high-volume models (at least 1% of total exposure) heading the list of "best cars" were: Oldsmobile Delta 88 (55), Chevrolet Caprice (64), Buick LeSabre (65), Chevrolet Impala (75), and Chevrolet Nova (79). Figures in parentheses are index numbers of relative claim frequency/1000 insured vehicle years; 100 represents the average injury claim frequency for all 1978 models. On the list of 1978 cars with the worst injury claim frequencies were: Honda Civic (144), Toyota Corolla (142), Datsun B-210 (140), Ford Mustang II (133), and Toyota Celica (131). Four of the five "best" 1978 models were also among the 1977 models with the best results, the 1978 Nova being the exception. Two of the five "worst" 1978 models (Toyota Corolla, Datsun) were also among the 1977 high-volume models with the worst results. A low-volume listing in the report for 1977 models (less than 1% exposure) indicated that the Datsun 200 SX two-door had the worst claim frequency results, and the Chrysler Newport four-door the best. The HLDI report reinforced earlier findings of higher claim frequencies with young drivers and smaller cars; higher claim frequencies with two- vs. four-door cars; and highest claim frequencies for sports and specialty models (subcompact/compact/intermediate sizes), especially with young drivers.

AN EVALUATION OF PICTOGRAPHIC SYMBOLS FOR CONTROLS AND DISPLAYS IN ROAD VEHICLES. FINAL REPORT

The recognition value of 25 symbols developed by the International Standard Organization for controls and displays in road vehicles was investigated using 125 subjects (75 males, 50 females) with more than one year of driving experience. The study demonstrated the high recognition value of 20 of the 25 symbols which, in general, is not influenced by sex or additional military driving experience. The five symbols which failed the acceptance criterion of a minimum 75% recognition are: LIGHTER, CHOKE, MASTER LIGHTING SWITCH, REAR FOG LIGHT, AND FRONT FOG LIGHT. It is assumed that the symbol for LIGHTER is of less importance and will be recognized after its initial use. Discrimination between FRONT FOG LIGHT and REAR FOG LIGHT can be improved by rotating the latter symbol 180 degrees. One symbol for FOG LIGHTS would be preferable because under fog conditions both lights will be turned on. The symbol for MASTER LIGHTING SWITCH should be redesigned to avoid confusion with INTERIOR LIGHTING. The symbol for CHOKE should be redesigned, perhaps to replace the pictograph with a verbal label.

HOW TO SURVIVE...WHEN YOUR CAR TURNS INTO A TRAP

Safety advice is provided for the motorist for surviving three types of freak accidents: caught in a burning car, trapped by a falling power line, and imprisoned in a car that has plunged into deep water. Safety experts say that a motorist can survive these emergencies in many cases, although some of the survival techniques themselves carry risks. If a hot wire falls on a car, the advice is to stay inside the car and await help, if possible; to warn other motorists to keep away; to assume all surfaces are electrically charged; and if it is necessary to exit (e.g. because of fire), to jump as far away as possible from car without touching it after feet are on the ground. It is emphasized that any kind of movement near a live wire can be risky. If a car catches fire, it is advised to shut off engine, take a moment to locate the fire (if in the upholstery, open windows fast); to get out fast; if the fire is in the engine, to beware of a hot blast when opening the hood, and to fight fire with extinguishers from opposite sides ("double team") if possible. It is advised not to fight a gas tank fire with an extinguisher. If a car plunges into deep water it is advised to remember that most cars float for a minute or two, usually right side up; to get out via the windows, sunroof, deck, or hatch as soon as possible (do not try to open doors); to remember that a car sinks toward the engine and an air bubble may form at opposite end; if unable to exit car before it starts to sink, to turn on lights if possible. After the car has hit bottom, and water inside car has risen above the doors the occupant may open the door and swim to safety (or if doors are jammed, shatter a window).

AUTOMOTIVE GAS TURBINES: WHERE DO THEY STAND?

Although the gas turbine has been explored for application to automobiles, trucks, and buses for 30 years, a production gas turbine engine has not yet been realized. Gas turbine problems are becoming increasingly difficult, expecially in the small engine sizes required for automobiles. Among these problems are lower aerodynamic efficiencies resulting from scale effects, larger boundary layers, increased flow blockage, higher thermal gradients due to smaller heat sinks, increased relative blade tip clearance, and minimum blade thicknesses; and lower reliability (than for large gas turbines) due to increased structural, mechanical, and thermal fatigue, and higher thermal stress, resulting from the increased high-frequency excitation of higher rotating speeds. Higher costs are the result of tighter tolerances, thinner blading, smoother surface finishing, more costly materials, larger speed reduction, and variable geometry (nozzles, inlet guide vanes, etc.). The key obstacles to gas turbine engine in automotive applications are essentially the unavailability of low-cost, high-temperature materials such as ceramics, and the aerodynamic inefficiency of small turbomachinery.

ROTARY ENGINE'S LIGHT-LOAD COMBUSTION IMPROVED

Experimental investigations by Toyota engineers of correlations between ignition and combustion chamber gas composition, together with the processes of internal EGR (exhaust gas recirculation) have resulted in improved light-load combustion in Toyota's Stratified Charge Rotary Engine. The internal EGR in rotary engines sometimes results in excessive misfiring under idling conditions, producing poor driveability and lowered fuel economy. Toyota engineers isolated sources of misfire according to their location in either of two plugs or the combustion chamber itself. By adopting both air injection at the exhaust port and glow ignition, a drastic reduction in fuel consumption at idle was possible, as well as beneficial effect on driveability in the low-speed range. In addition to these improvements at light load, nitrogen oxides (NOx) formation was suppressed in higher load ranges by adjusting the internal EGR via stopping the air injection and supplying a leaner mixture to decrease reaction at the glow plug. With these countermeasures, good data are obtained without using external EGR for the stringent Japanese 10-mode emissions test. Toyota data indicate the engine in carbureted form has demonstrated the ability to meet 1981 U.S. emission standards of 0.41/3.4/1.0 g/mi of hydrocarbons, carbon monoxide, and NOx using only an oxidation converter as aftertreatment.

BRAKE APPORTIONING VALVE SENSES DECELERATION

Researchers at Girling have designed deceleration-conscious apportioning valves suitable for passenger car and light-truck applications. These inertia-controlled ball reducing valves achieve load-conscious behavior without the need for load linkages. The G-valve is pressure-conscious, the GP-VALVE is pressure-limiting, and a third valve is height-sensing. These apportioning valves help improve vehicle stability during braking. The optimum selection of valve type must be resolved by consideration of functional factors (vehicle characteristics, brake equipment, wheel cylinder size, lining friction variation, valve installation, and legal requirements), as well as economic factors. Adhesion utilization curves have shown that G and GP valves fulfill all legal requirements for all passenger cars including front-wheel drive vehicles with maximum load variations.

FALL CAR CARE GUIDE, SERVICE TIPS

Service tips are provided for the car owner on lubrication, ignition, fuel system, emissions control, battery, and brake system. The functions of motor oil and filter and intervals between changes are discussed; viscosity number, multigrade vs. single grade oil, and American Petroleum Inst. oil classification system are explained; step-by-step instructions (and some illustrations) are provided for changing oil and filter. Procedures are outlined for inspecting fluid levels in the brake master cylinder, automatic transmission (according to manufacturer), and cooling system. Step-by-step instructions are given for lubricating chassis ball joints. A checklist is provided of other car parts that should be lubricated when the chassis is greased, as well as those that may require lubrication. Step-by-step instructions are given for inspecting various components of the ignition system: ignition coil, distributor cap, high-voltage (secondary circuit) cables, as well as for replacing spark plugs, and setting ignition timing. Fuel system maintenance covers the function, types, and changing of fuel filters. Step-by-step instructions are given for replacing the three types of fuel filters (in-line, internal, and combination). Instructions are given on servicing carburetor air filters and chokes. Emission control information includes servicing the fuel evaporation canister, positive crankcase ventilation system, thermostatic control valve, and exhaust gas recirculation valve (according to manufacturer). Battery maintenance includes safety, inspection, removal, cleaning (battery and cable terminals and battery posts), and quick battery check. Instructions for inspecting brake linings (pads), cylinders and lines are outlined and illustrated. Transmission and tire/wheel servicing are briefly discussed (service intervals and checks for transmissions, and tire/wheel inspection and tire rotation and inflation).

ARGUMENT CLOUDS GASOHOL ISSUE

While gasohol (90% gasoline, 10% ethanol) is a much inferior fuel to gasoline, it is considered the best alternative fuel available today. Gasohol can and probably will make a small, but significant contribution to the U.S. automotive fuel supply in the next decade, although gasohol's role could be expanded or diminished by major changes in the availability and price of gasoline or by new technology in gasohol production. To reduce the daily consumption of gasoline in the U.S. by 10%, or 18.9 million gallons, an almost 100-fold increase in ethanol production would be required. One important advantage of ethanol is its role in the U.S. economy (trade balance). It is also a renewable resource, produceable from many agricultural products. General Motors and other organizations feel that gasohol's main attribute is as an indicator of the seriousness of the oil shortage. The Dept. of Energy says that a net liquid fuel gain can be achieved when oil or natural gas are not used as a power source for alcohol production. Recent government and industry studies have found that late model cars running on gasohol will get 1% to 3% less mileage than those running on gasoline, and that gasohol use reduces carbon monoxide emissions but increases hydrocarbon, aldehyde, and nitrogen oxides emissions. Other gasohol problems relate to driveability, and fuel phase separation. Starting in 1981, however, U.S. cars should be better able to use gasohol because of electronic control of the fuel-air mixture, thereby compensating for alcohol effects on driveability and emissions. Although gasohol costs more than gasoline today, subsidies and special tax advantages are in effect to stimulate its use.

GOVERNMENT ROADMAPS BASIC AUTO RESEARCH

Highlights are presented of a personal interview with Howard Dugoff, deputy administrator of the National Hwy. Traffic Safety Administration, concerning the cooperative government-industry automotive research program for which he has been appointed to the task of planning and coordinating. The program seeks to adopt a more sophisticated fuel economy technology and to develop a socially responsible automobile. Industry and government will share an annual research bill estimated at $50 to $100 million for projects assigned to university, industry, and Federal laboratories. Mr. Dugoff said that his first priority is to reach an agreement on a framework for the program. Critical issues relate to funding, and the extent and nature of coordination among participants. One general agreement is that there should be a somewhat independent oversight or advisory group. It is anticipated that scientific developments would be applied either voluntarily by the auto industry to meet consumer demand or, in the event of continued regulation, to help the industry comply more efficiently and effectively. The philosophy of the program is that the Federal government will make the initial contribution to advancing basic research, after which the industry, with its technological resources and business acumen, will take over in developing a new product. The ultimate objective of the program is an automobile with good fuel economy, low emissions, and a high level of safety and damageability (low cost to repair).

TRANSPORTATION AND THE CITY, GRADES 8, 9. INTERDISCIPLINARY STUDENT/TEACHER MATERIALS IN ENERGY AND THE ECONOMY

A packet of learning activities (teacher's manual, student guide) has been designed to fit into existing segments of instruction in U.S. history and civics courses at the middle school level. The first activity, entitled "Getting There," enables the student to hypothetically select his "dream" car and evaluate the mpg he will obtain with its use. It is intended that the student determine whether he can afford this car and that he consider alternate means of transportation (i.e. mass transit systems). The second lesson, entitled "Shut Down by Tin Lizzie," acquaints the student with some of the changes the autombile brought to the U.S. small town. The student is asked to think about the ways people live together and the quality of life; these are often affected by rapid change. The third unit, entitled "The City of Windshields," focuses on Los Angeles and some of the effects of the automobile on the design of the city and on the everyday lives of the people who live there. The final activity, entitled "The Car on Trial," asks the student to investigate the problems caused by the car in the U.S. and to weigh the merits of the car against the problems it has produced. The teacher's manual covers the following topics: overview, objectives, target audience, materials, time allotment, teaching strategies, and student questions. The student guide contains text, charts, tables, questions, and exercises.

ALCOHOL AND OTHER FACTORS IN FATAL MOTORCYCLE COLLISIONS: A PRELIMINARY ANALYSIS

In an effort to determine whether differences existed in the characteristics of collisions involving motorcycle drivers classified as sober, had been drinking, or impaired, 214 fatal motorcycle accidents were examined in terms of eight driver/crash variables: driver age and occupation, hour of crash, collision type, victim action, accident location, and road surface and type. Four variables (age, action, hour, and collision type) were found to be significantly related to BAC (blood alcohol concentration) and to account, in aggregate, for 32% of the variance in BAC. Age and BAC were found to have a curvilinear relationship, such that increases in age were associated with higher average BAC'S up to age 20-24, beyound which mean BAC decreased with age. Average BAC's for daytime fatalities were substantially lower than those for nighttime fatalities. Mean BAC for persons killed, when their driving action was judged in error, was significantly higher than that of victims whose action was judged correct. Victims of single-vehicle crashes had, on the average, significantly higher BAC's than victims of multiple-vehicle collisions. The results of this study confirmed the overrepresentation of young drivers among fatally injured motorcyclists, but did not confirm the presence of low BAC's among this group.

LIGHTER AND LIGHTER. 2ND ANNUAL PLASTICS REFERENCE (AUTOMOTIVE APPLICATIONS)

New plastic materials and processing advancements are examined which are heralding the introduction of an increasing number of lightweight structural and functional plastic parts for U.S. automobiles in the 1980's. Ford is concentrating on compression and injection molding, to reach its near-term objective of adding 90 to 140 lb of plastic to each car by 1985. The first graphite-fiber-reinforced plastic composite part will be an air conditioner mounting bracket on some 1980 Ford cars equipped with 2.3 L engines. Suspension and structural parts, and prop shafts are likely future applications of the graphite composite. A foam backing has been developed for a new General Motors (GM) one-piece headliner unit. The foam, called Amocor (Amoco Foam Products Co.), is thermoformable. Future applications may include rear shelves, angel wings, and door panels. General Electric has developed a family of epoxies with characteristics that eliminate most processing problems; this new type of epoxy will remain in a moldable consistency until a critical temperature is reached. For the first time, epoxy resins will be able to handle a number of processes. Arnox series 3000 liquid resins will likely be the first epoxies to meet automotive part mass production requirements. Currently forecast by GM to reach around 255 lb per car by 1985, plastic use could reach 300 lb if some technological obstacles are overcome. In the international market, a number of plastic resins developed by the Anic company (Italy) are being used in various automotive applications (e.g. seat shells, radiator grilles). Scott Paper Co.'s polyurethane foams are being used for four basic automotive functions: filtration, sound absorption, reservoiring/delivering, and cushioning. A major weight-saving feature of Chrysler's 1980 model line is a bumper guard system on the Chrysler 300 and Dodge Mirada models, which uses a urethane "bun" vs. a hydraulic system. GM's X type cars contain a new window regulating system which relies on a new elastomeric polyester "EPS" tape, and a number of other Du Pont resin parts.

DEVELOPMENT OF A SELF-POWERED VEHICLE DETECTOR. FINAL REPORT

A prototype Self-Powered Vehicle Detector (SPVD) was developed to eliminate the lead-in or interconnecting cables associated with conventional vehicle detectors. The battery-operated detection system detects a vehicle's magnetic signature, processes it, and then transmits vehicle presence information from its roadway position to a nearby receiver control unit. The SPVD requires minimum installation time and cost, little maintenance, and is capable of detecting vehicles on any standard roadway surface. The system consists of two units, the roadway implanted sensor and a control unit, located inside a traffic instrumentation enclosure less than 500 ft away. The SPVD sensor unit is placed in a standard roadway bore hole located in the center of the lane just beneath the surface. The estimated lifetime for a traffic flux of 20,000 vehicles/day is greater than one year. The development of the sensor (magnetometer), FM transmitter, microstrip antenna, and digital encoder/decoder circuitry is described. Also included are FM-receiver and sensor power source (battery) evaluations as well as SPVD fabrication schematics, drawings, and printed circuit artwork.

SOME SPECIAL FEATURES OF THE TURBOCHARGED GASOLINE ENGINE

The influence of compression ratio, temperature of the charge air, and ignition timing on the performance of the turbocharged (TC) gasoline engine is discussed, as well as the importance of recooling the charge air and setting the ignition timing very precisely. Calculations of the realistic effective efficiencies for a TC and a naturally aspirated gasoline engine of about the same power output show the advantage of the TC engine. The interaction of compressor and engine is examined through a compressor/engine air flow map of the TC gasoline engine, and comparisons are made with the TC diesel engine. The features of a compressor matching the special requirements of a TC gasoline engine are deduced from the map. The position of the throttle in the intake system is discussed, which has a great influence on governing qualities and load-change response of a TC gasoline engine. A main problem of the TC gasoline engine appears to be that of regulating the charge pressure while maintaining turbine efficiency. Adjustment of charge pressure by means of a waste-gate is rejected as an approach for the TC gasoline engine.

PLASTIC COMPONENTS FOR WINDSHIELD WIPER SYSTEMS

The gradual adoption of plastic components in the mechanisms of windshield wiper systems, as acceptable materials have become available, is described. Plastic material developments have brought designers desirable characteristics, such as higher tensile strength, resistance to fatique, service at greater temperature extremes, lower coefficient of friction, self-lubrication, electrical insulating properties, and resistance to heat aging, oxidation, and weathering. A windshield wiper set, consisting of motor, linkage, arms, and plastic blades, now contains 8% plastic by weight. A washer set, consiting of pump, reservoir, and nozzles, contains 73% plastic by weight. These percentages are leaders in the use of plastics in the automotive industry (a typical 1978 model car contains 5% plastic by weight). The plastic wiper blade, as an example of one application, offers the following qualities: uniform cleaning of windshield throughout the length of the blade over various windshield curvatures and with wide range of wiper arm loads specified by car manufacturers for different models, reversal of element at start of wiping stoke, low friction, windlift resistance, quiet operation, endurance, and weight reduction.

CARBURETOR DEPOSITS AND THEIR CONTROL

The effects of unleaded gasoline properties on the formation of carburetor deposits were studied by analyzing data from six field tests and by conducting a laboratory engine test program to investigate a wide range of gasoline properties. It was found that stable, low gum content, nonadditive-containing, unleaded gasolines form deposits throughout the carburetor in field tests independent of vehicle type, service, or tested gasoline properties. Sulfur, nonbasic nitrogen, and existent gum in gasoline increase carburetor throttle body deposits, but carburetors are not deposit-free when these components are essentially eliminated. Olefins in gasoline and 10% and 90% evaporation temperatures also adversely affect throttle body deposits. The only current practical way to control carburetor deposits of volatile, stable, low gum content gasolines is to use an effective DC (deposit control) additive. Such an additive can also clean up and keep clean critical areas of a new design variable venturi carburetor. Fleet fuel economy differences are difficult to determine unless many cars are on test or unless operation and maintenance variables are closely controlled. In one test, an mpg benefit of about 2% was found for a DC additive-containing fuel over nonadditive, unleaded gasoline.

THE EFFECTS OF FUEL COMPOSITION AND FUEL ADDITIVES ON INTAKE SYSTEM DETERGENCY OF JAPANESE AUTOMOBILE ENGINE

Fuel composition and additive (antioxidant and detergent) effects on intake system cleanliness were studied using Japanese automobile engines equipped with exhaust gas recirculation systems. It was found that deposit formation in the intake system (carbuetor and intake manifold) is likely to be greater when the engine is operated at medium speed and medium load. Higher fuel olefin content markedly increases deposit formation in the intake system, and antioxidants can increase deposit formation. Fuel aromatics do not adversely affect carburetor or intake manifold cleanliness. A detergent greatly improves carburetor and intake manifold cleanliness, but shows little or no effect on intake valves. The cleanliness effect of a detergent additive is greater when it is used with a "dirty" base gasoline. Intake valve deposits are greater with higher olefin fuels. Aromatics do not affect total deposits but increase the ratio and weight of the organic insoluble portion. Carrier oil/detergent combinations markedly reduce intake valve deposits. An increase in the aromatic content of the fuel appears to augment cylinder head deposits.

A NOVEL LABORATORY METHOD FOR EVALUATING INDUCTION SYSTEM DEPOSITS IN GASOLINE ENGINES

A laboratory bench rig procedure has been developed for the evaluation of dispersant-detergent gasoline additive effectiveness used for the control and/or inhibition of carburetor and engine intake system deposits. The development of a synthetic crankcase off-gas liquid made possible the bench procedure which provides data that correlate with actual engine results in the carburetor throttle plate and throat area, in the induction system (port and valve areas), and in additive effectiveness. The repeatibility of the procedure is good, and the apparatus, simple in design and operation, permits simultaneous evaluation of carburetor and intake deposits. The fuel requirement is small (1080 ml), and the test can be run in an 8-hr working day. The air-fuel mixture impinges on the depositing surfaces at (scrubbing) velocities found in an intake system. The temperatures of the depositing surfaces are comparable to those found in the carburetor (cold) and at the intake valve and/or port areas (hot). A broad evaluation-correlation of dispersant-detergent additives to actual engine test fleet operations is necessary for validation purposes. Additional work is recommended on carburetor sleeve design.

NEW 5- AND 6-CYLINDER VW DIESEL ENGINES FOR PASSENGER CARS AND LIGHT DUTY TRUCKS

The diesel engine line of the Volkswagen Group has now been expanded from the VW Rabbit 4-cylinder engine to 5- and 6-cylinder engines developed for passenger cars (Audi 100) and light-duty trucks (VW LT truck line), respectively. As in the 4-cylinder version, these engines employ the swirl chamber process. They are in-line, overhead camshaft configurations with bucket tappets and with valves parallel to the cylinder axis. Cylinder volume is 400 cu cm. Power output of the 5-cylinder engine is 50 kW, with 60kW for the 6-cylinder engine, both at a rated speed of 4800 rmp. Cast iron cylinder blocks and aluminum cylinder heads are used. The basic design, development highlights, and performance characteristics (e.g. power, durability, emissions, and fuel economy) are described for the two engines. The VW/Audi diesel-powered vehicles meet all emission standards for the 1979 model year, worldwide. Additional technology development is required to ensure compliance with future U.S. emission standards for nitrogen oxides and particulates. Further improvements need to be made with regard to driver comfort, idle noise, and elimination of preheating time requirements. Current developments in exhaust gas turbocharging are promising for increasing the power output of the diesel to that of present naturally-aspirated gasoline engines. The diesel-powered vehicle offers better fuel economy than its gasoline-powered counterpart.

THE CRIMINAL USE OF FALSE IDENTIFICATION. A SUMMARY REPORT ON THE NATURE, SCOPE, AND IMPACT OF FALSE ID USE IN THE UNITED STATES WITH RECOMMENDATIONS TO COMBAT THE PROBLEM

Surveys were conducted and an examination was made of the extent of false identification (ID) use in the U.S. in six major problem areas: drug smuggling, illegal immigration, fugitives from justice, fraud against business, fraud against government, and other criminal activity. Common identification documents include: birth certificate, driver's license, U.S. passport, U.S. visa and alien ID card, Social Security card, Selective Service draft card, voter registration card, credit cards, and nongovernment ID. Findings, background material, recommendations, and plans are presented for implementing the proposed solutions of the Federal Advisory Com. on False Identification (FACFI). Appendices offer a comprehensive source of current information on the false ID problem: FACFI Task Force reports, four background papers by the MITRE Corp. (three reports on technological aspects of the personal identification problem, and a broad survey of the false ID problem as perceived in several foreign countries); descriptions of programs developed by MITRE (under contract to the Law Enforcement Assistance Administration) for reducing the abuse of birth certification, for matching birth and death certificates, and for improving driver's license security; and a proposal by Polaroid Corp. to upgrade driver's license security. Additional appended material includes excerpts from an underground publication on techniques used in false identification; a letter from the Western States Bankcard Assoc. on false ID fraud, a summary of Federal laws relating to false ID, and three responses received by FACFI expressing strong disagreement with specific committee findings or recommendations.

CONCURRENT PHYSIOLOGICAL ACTIVITY OF DRIVER AND PASSENGER WHEN DRIVING WITH AND WITHOUT AUTOMATIC TRANSMISSION IN HEAVY CITY TRAFFIC

Twelve subjects were selected for a comparison of driver and passenger psychophysiological reactions in vehicles with automatic transmission and with manual transmission in heavy city traffic. Each subject underwent four test runs, as a driver and as a passenger with each transmission. The physiological parameters recorded from driver and passenger were urinary excretion rates of adrenaline and noradrenaline, skin conductance responses (SCR), skin conductance levels (SCL), electromyograms (EMG) from the forehead muscles, and electrocardiogram (ECG). Each test run on the 14 m circuit course consisted of four complete circuits. In drivers, significant differences were found only between driving with automatic and manual transmissions. Other factors, such as sequence of testing or time of day, had no significant effects. When driving with manual transmission, rate of adrenaline excretion, SCR, heart rate, and heart rate variability were significantly higher than when driving with automatic transmission or riding as a passenger. No significant differences were observed between these two situations. The passenger situation resulted in significantly lower muscle tension than either driving situation. A comparison between first and second runs showed significantly lower values for SCR, muscle tension, and heart rate of passengers on the latter. It is indicated that central arousal rather than physical workload is the major factor responsible for the differences between driving with manual and automatic transmissions. In the driving situation, this defense-alarm reaction can be inappropriate. Physically, the driver has to remain rather passive, although his physiological arousal level is in a state ready for a stronger physical activity.

In city traffic, stress reduction due to the use of an automatic transmission may constitute a valuable measure for improved health and traffic safety.

HS-027 186

ADULT AGE AND THE SPEED-ACCURACY TRADE-OFF

The possibility was investigated that previously reported age differences in speed performance were caused by older subjects placing more emphasis on accuracy than younger subjects. The speed and accuracy with which three different samples of young and old subjects performed variations of a manual task (pressing different buttons in response to lighted lamp patterns) were recorded and analyzed statistically. The major conclusion is that while a greater emphasis on accuracy rather than speed is definitely a factor contributing to the slower performance of older adults, it probably cannot account for all of the age differences in speed of performance. A speed-accuracy tradeoff did seem to be responsible for all of the age differences observed in one experiment, but sizeable age differences remained after the elimination of differential accuracy biases in the second and third experiments. The differences observed across experiments serve to emphasize the importance of sample specification in research on aging. Although it appears that the speed-accuracy tradeoff procedures can make only a limited substantive contribution to the understanding of age differences in performance speed, the methodological contribution seems unlimited. Speed-accuracy operating characteristics do not have the interpretation problems associated with traditional reaction time measures, and can be obtained in naive, unpracticed subjects; the procedures are therefore valid for research on individual differences. It is highly recommended that subsequent research use these procedures to quantify factors related to age difference in speed.

MECHANISMS OF THE EFFECTS OF VIBRATION FREQUENCY, LEVEL AND DURATION ON CONTINUOUS MANUAL CONTROL PERFORMANCE

Three experiments were performed to investigate the effects of vibration frequency, level, and duration on a zero order, pursit tracking task, and the mechanisms responsible for these effects. The first experiment investigated the effect on tracking performance of vertical, sinusoidal vibration of the control stick in the frequency range 4 to 64 Hz. Control dynamics were either isotonic (displacement), isometric (force) or spring-centered. The second experiment investigated the effect of level of vertical, 4 Hz and 16 Hz whole-body and control vibration on performance with the isotonic and isometric controls. A third experiment investigated the effects of duration of continuous, vertical, whole-body vibration at 4 Hz, for durations up to 1 hour, on performance with the isotonic and isometric controls. Performance measures included closed-loop transfer functions of the human operator and components of mean-square tracking error correlated with the forcing functions and vibration, and those due to operator-generated noise or remnant. The results indicate that the primary effects of vibration on the tracking task were increases in remnant and vibration-correlated error. Perceptual and motor sources are suggested for the increased remnant. The effects were largest with 4 Hz vibration and were found to be effectively constant throughout 1-hour exposures to continuous 4 Hz whole-body vibration, but after relatively short periods the effect on overall tracking performance was effectively masked by large increases in response lags and suppression of coherent responses which occurred in both static and vibration conditions as a consequence of diminished levels of arousal.

FUEL MOTION AND POLLUTANT FORMATION IN STRATIFIED CHARGE COMBUSTION

The concept of charge stratification is examined, using a numerical model for fluid mechanics and chemical kinetics. Initially homogeneous and stratified charge cases are discussed and compared, and simplified global rate expressions for the chemical reactions are compared with a detailed reaction mechanism. Results computed for the stratified models indicate that the fuel can be completely burned before it reaches the walls of the combustion chamber, effectively eliminating wall quenching as a source of unburned hydrocarbon emissions, but volume flame quenching appears to result in unacceptably large amounts of unburned fuel in the stratified models.

SPEED LIMITS. SAFETY SUCCESS OR MUDDLED MEDDLING?

Evidence for urban and rural speed limits in Great Britain is reviewed, and the concept that they help prevent accidents is disputed. The saving in fuel brought about by lower speed limits is also described as negligible. Since in Britain the majority of all accidents, including serious and fatal accidents, take place in built-up areas, the overall influence of an open-road limit must be small. A 1967 investigation in America found that the accident involvement rate is lowest at about the average speed of all traffic and highest at very low and very high speeds. In a recent study of overtaking maneuvers the basically accepted correlation between speed and seriousness of injuries is not reflected. It is contended that any accident reduction claimed as a result of the 50 mph limit imposed was actually a result of the reduction in traffic flow caused by the oil crisis, with its resultant shortage and higher cost of gasoline. A reduction of accidents in urban areas following the introduction of the original 30 mph limit in 1935 is attributed to major road improvements and other safety measures. A 1973 review by the Metropolitan Police of speed limits on London's main roads recommended retention of the 30 mph limit on residential roads but allowing higher limits on 176 miles of London's roads with limits changed in one or two cases from 40 mph to 70 mph. To illustrate the improvement in wet-road braking performance between modern cars and those of the '30s, a comparison test was run with a recording fifth wheel. Due to the marked inferiority of their tires and brakes, the cars typical of 1935, when the 30 mph speed limit was introduced, proved far worse at stopping on a slippery surface than modern cars; it is therefore argued that the urban speed limit could safely be raised to 40 mph.

MODEL FOR NITRIC-OXIDE FORMATION IN A LARGE-BORE SPARK GAS ENGINE

In order to better appreciate the effects of various combustion factors on NOx formation in stationary, reciprocating spark-ignition engines, a phenomenological model of combustion in a 20-inch bore two-cycle natural gas engine is described. Several characteristics distinguish the combustion in large-bore engines from ordinary automotive engines: low rpm and associated long combustion duration, natural gas fuel, multiple spark plugs, lean operation, substantial unmixedness due to direct gas injection during compression, and low surface to volume ratio. All the combustion conditions which make large-bore engines relatively efficient prime movers also make them produce relatively high levels of NOx. This study is part of a long-range research program to develop combustion modifications for 1985-1990 models of large-bore engines. The model accounts for "unmixedness" of the initial charge, stratification, and temperature gradients arising from successively burned zones. Predictions are compared with experimental data for the effects of variations in timing, fuel-air ratio, stratified charge, EGR, and turbulence; these indicated the possibility for substantially reduced NOx emission levels under a variety of operating conditions.

LOW-VOLUME ROADS: SECOND INTERNATIONAL CONFERENCE

Forty-one papers are compiled, related to highway engineering and technology of low-volume roads. Subjects covered include types of road surfaces and maintenance experiences, bridge inventory and inspection, low water crossings, a durable reflective sign system, and earthwork practices in cold weather. Also discussed are integrated rural road systems and road network analysis, evaluations of road roughness and its effect on vehicle operating costs, fuel consumption related to vehicle type and road conditions, road improvement measures, and highway safety requirements. Reports are contributed by developing countries as well as those with longer experience in highway maintenance, including Australia, Barbados, Bolivia, Brazil, Egypt, Gambia, Israel, New Zealand, Republic of South Africa, Tanzania, Thailand, U.K., and U.S.A.

EFFECT OF SIMPLE ROAD IMPROVEMENT MEASURES ON VEHICLE OPERATING COSTS IN THE EASTERN CARIBBEAN

The effect on vehicle operating costs of a simple labor-intensive method of rehabilitating and maintaining badly deteriorated bitumen surfaced roads in the Eastern Caribbean is described. The techniques developed for the rehabilitation and maintenance of the roads are described, and the equipment, materials and manpower required are listed. The system is a simple one, restricted to providing adequate drainage, filling the potholes in the road and providing a minimum seal over the whole road surface. The most effective method of surface dressing was found to be labor-intensive sandsealing. In this method, RC 2 bitumen is poured on the road surface at a rate of approximately 0.27 litres/sq metre (0.2 gals/sq yard), spread with rubber squeejees, then covered with a layer of sand 25 to 30 mm thick; the sand is then lightly rolled. The reduction in vehicle operating costs resulting from the improvement in the riding quality of the road surface is sufficient to recover the rehabilitation costs in a short time, even at flows as low as 100 vehicles a day. Most roads in this plan are of low strength and geometric standards, and have traffic flows ranging from 50 to 1500 vehicles per day. All the roads have been trafficked for at least one year since rehabilitation and some for two with little or no damage to the surface. Maps and photographs are included.

HIGHWAY SAFETY REQUIREMENTS FOR LOW-VOLUME RURAL ROADS

A study was made to reevaluate the safety needs on low-volume rural (LVR) roads. Based on a series of functional analyses relating safety performance to specific design and operational elements, a set of revised guidelines was developed. These guidelines, which apply to total roadway width, horizontal curvature, roadside design, speed signs, curve warning signs, centerline markings, and no-passing stripes, are proposed to supplement the existing national policies, either replacing or clarifying the existing national guidelines. The widespread application of the revised guidelines should provide for more consistent design and traffic control of LVR roads consonant with a raional balance between highway investment, highway safety, and traffic service. Two basic kinds of studies are recommended to continue this research: those to collect accident data on LVR roads for a clearer picture of their current safety performance, and those to collect on-site data of LVR traffic characteristics, to verify the revised safety requirements.

A DURABLE REFLECTIVE SIGN SYSTEM FOR LOW-VOLUME ROADS

Due to extreme temperatures and snow burial, the reflective sheeting often peels from the signs on National Forest park land after only one winter. In 1972 the Forest Service Missoula Equipment Development Center began testing outdoor signs of various substrates, reflective sheeting, application techniques, and clear coatings, hoping to produce a reflective sign that would remain maintenance-free for seven years. After five winters of outdoor exposure, several combinations of sign material were rated free of structural failure that would require maintenance. The following materials and techniques were recommended in manufacturing outdoor reflective signs for Forest Service use: engineering-grade sheeting and letters with heat-activated adhesive (HA) on aluminum substrate, cycled twice through the heat vacuum applicator and clear coated; engineering-grade sheeting (HA) and pressure-sensitive (PS) or HA letters on high-density overlay (HDO) plywood substrate, cycled twice through the heat vacuum applicator (when PS letters are used, the sheeting is cycled through the heat vacuum applicator once before applying the message and once after); high-intensity sheeting (PS) with heat-activated letters on HDO plywood substrate, cycled once through the heat vacuum applicator. Signs are equally durable with silk-screened letters. The top edges of all signs are protected with Scotchcal brand transparent film. Photographs and data tables are included.

THE EFFECT OF ROAD DESIGN AND MAINTENANCE ON VEHICLE OPERATING COSTS. FIELD RESEARCH IN BRAZIL

The design and methodology of the survey of vehicle operating costs on rural and inter-urban roads in a large area of central, western, and southern Brazil is described. Data were collected from 117 operators for 1326 vehicles by a team of 20 researchers. Road roughness and geometric characteristics were measured on 423 routes totalling nearly 40,000 km in length, using two specially instrumented cars. The method of analysis is explained and some preliminary relationships are presented and discussed. Special attention is given to depreciation and vehicle maintenance costs. An example is used to show that on typical unpaved roads, increases in fuel consumption are smaller than on paved roads in relation to the overall increase in costs. Road geometry appeared to have powerful effects on fuel consumption while road roughness had the most important influence on total vehicle operating costs. Analysis will continue until Nov 1979.

RELATING VEHICLE OPERATING COSTS TO LOW VOLUME ROAD PARAMETERS IN BRAZIL

An overview is given of a 12 million dollar research study, jointly supported by the Brazil Ministry of Transport and United Nations Development Program, to determine the relationships between vehicle user costs, roadway design standards, and maintenance policies for low volume roads. The relationships are based on an analysis of data generated in a survey of vehicle users operating on over 60,000 km of homogeneous paved and unpaved routes. Up to two years of user costs data have been produced on over 1200 vehicles, together with 450,000 observations based on radar speed measurements of vehicle behavior plus fuel measurements from nine project test vehicles. Data developed from 187 paved and unpaved roadway test sections are being used to develop equations to predict road performance. The relationships between vehicle-operating costs and roadway characteristics, traffic and environmental conditions are being incorporated into a computer-based planning model, MOBAIR, to be used for evaluating alternative highway transportation strategies. Charts and diagrams illustrate aspects of the study.

FUEL CONSUMPTION RELATED TO VEHICLE TYPE AND ROAD CONDITIONS

An investigation of the effect of road condition and vehicle type on fuel consumption was conducted in Brazil. A test fleet of nine vehicles ranging from a Volkswagen to an articulated truck was used to perform nine experiments. Roadway characteristics studied include horizontal curvature, grade, surface type, and roughness. Vehicle operating modes studied include constant speed, acceleration, deceleration, and deceleration due to gravity. An experiment was also performed on the effect of adding 20% alcohol to gasoline, which resulted in an increase in fuel consumption of approximately 10%. Regression equations for predicting fuel consumption as a function of speed and vehicle and roadway characteristics were developed for constant speed operation. These equations, one for each vehicle type, show that fuel consumption is exponentially related to speed, weight, gear, grade, and surface roughness. Curves of 72 m in radius did not have a significant effect on fuel consumption. Charts and graphs illustrate the study.

PREDICTING TRAVEL TIME AND FUEL CONSUMPTION FOR VEHICLES ON LOW-VOLUME ROADS

A major expermental investigation of the effect of roadway characteristics and environmental conditions on traffic behavior was conducted in Brazil. Empirical relationships were developed for predicting free speeds on positive and negative grades. Free speed was found to be related to vehicle class, grade, surface type, and road roughness. These relationships have been incorporated into a computer program, TAFA, for predicting travel time, free speed, and fuel consumption on low-volume rural roads. Example applications of the model show its usefulness in evaluating operational and road maintenance strategies which are of interest to highway engineers and economic analysts.

MICHIGAN PUBLIC OPINION TOWARD MOTOR VEHICLE INSPECTION. FINAL REPORT

To assist the Michigan Dept. of Transportation in developing plans for a state motor vehicle inspection program, a state-wide public opinion survey of Michigan drivers was conducted. A sample of 999 drivers was contacted by telephone or mail between May and Aug. 1979, with an 86% response rate. The questionnaire focussed particularly on the desirability of emissions inspections and a slight plurality of the sample (47.9%) were in favor of such a program. Much larger proportions of the sample favored safety inspection (83%), noise inspection (67%), and a combined safety and emissions inspection (73%). More than half preferred that any inspection program be paid for by other state funds rather than by an inspection fee, and majorities in all parts of the state thought an emissions inspection program should be statewide if it were established. Complete survey results are included. Appendices include 45 tables, a narrative listing of interesting respondent comments, copies of the questionnaires and respondent letters, and some methodological notes.

CHANGEABLE MESSAGE SIGNS

A synthesis of detailed information on the effectiveness and application of changeable (variable) message signs was prepared for use by engineers concerned with traffic operations and control. Information is provided on requirements for design, installation, operation, and message effectiveness. Previous and current research is reviewed and future development needs are identified. A discussion of various types of displays is presented, followed by a description of control systems, surveillance, and interconnect techniques. Features of freeway traffic advisory and incident management systems are considered. Their applications include freeway-to-freeway diversion, special events notification, adverse road or weather conditions warning, and speed control. Areas of future technology research are discussed. Appended are potential applications of changeable message signs and known applications as of 1978.

SLIP THROUGH THE WIND. (AUTOMOBILE AERODYNAMICS)

Pininfarina, body builders and stylists for some of the best automobile manufacturers in Europe, attempted to define an aerodynamically-ideal car body in 1976. Researchers wanted to create a three-dimensional full-scale model, considering production constraints and prevalent standards. In addition to that offered by tires and mechanical components, aerodynamic resistance has been classified in terms of skin friction, profile drag, interior drag, and induced drag. Form drag is minimized in Pininfarina's model by assuring that the car body's cross-section varies gradually and that pressure variations along lines of flow are also gradual. Car stability depends on whether the center of pressure is in front of the center of gravity or vice versa. Simple alterations like rounding edges of a boxy car body can affect both the center of pressure and the magnitude of force induced by side winds. Pininfarina's basic shape has been tested in a wind tunnel, and interior studies have been conducted. Reduced fuel consumption has been demonstrated. Photographs are included. A separate section briefly describes the Citroen CX, the world's most aerodynamically advanced production car.

RED LIGHT FOR DRINK (SIC) DRIVERS

An electronic breathing device to screen drunk drivers is examined. Manufacturers of the Alcolmeter (Lion Labs, England) claim the device is accurate to within 10 mg of alcohol per 100 ml of blood and should reduce needless arrests and inconvenience to innocent motorists. The device is the size of a pocket tape recorder and incorporates an electrochemical fuel cell that generates voltage in proportion to the amount of alcohol in breath samples. If a red light flashes, this indicates the alcohol level in a sample is above 80 mg. Alcolmeters are compared with conventional breath analysis techniques. Their use in Sweden, Finland, Northern Ireland, the United States, and the United Kingdom is noted.

IT'S MOPED TIME!

The increased popularity of mopeds is addressed, with reference to maintenance and variations in laws governing their use. The Moped Association of America estimated 350,000 moped sales in 1979, a significant increase over 50,000 in 1975. Forty companies manufacture mopeds, including two U.S. companies (AMF and Columbia). Low-priced models cost about $400, while "luxury" mopeds cost about $630. Mopeds get over 100 miles to the gallon, some as much as 200 miles. A publication of the Arizona Governor's office of Highway Safety indicates that moped drivers are less likely to be involved in traffic crashes than motorcyclists; when mopeds crash, however, the rider's risk of injury is similar to that of the motorcyclist. The injury risk for drivers of motorized two-wheel vehicles in a crash is 10-15 times higher than for car passengers, and helmet use is strongly advocated. Of 33 States with special moped legislation, only New York has a helmet requirement for mopeds with a maximum speed above 20 mph. Lack of information on the potential danger of mopeds is noted. Maintenance problems are considered.

LAWS, LAWS AND MORE LAWS. STATE-BY-STATE SUMMARY OF MOPED LAWS AS OF AUGUST, 1979

Moped laws are summarized by state as of Aug. 1979. According to the Moped Association of America, all but six States have specific moped laws. Because laws governing the use of mopeds vary widely, a model moped law is being prepared for the National Hwy. Traffic Safety Administration by the National Committee on Uniform Traffic Laws and Ordinances. The summary of State moped laws presents tabular information on minimum age, license rules, registration requirements, speed limit, maximum engine limits, legal definition, mandatory insurance, and mandatory helmet.

WHY CYCLISTS SHOULD RIDE WITH TRAFFIC

The danger to bicyclists who ride facing traffic is emphasized. Studies show that wrong-way cycling is a leading cause of bicycle deaths and injuries. The purpose of traffic laws is to allow road users to rely on the predictability of each other's movements. Participation in traffic requires the cyclist to comply with laws which keep traffic orderly. Riding on the left upsets the orderly pattern. Hazards of wrong-way cycling are identified. The bicycle is a vehicle and this fact has both legal and practical implications. The wrong-way cyclist forces road users to deal with a hazard from a unexpected direction, and there are no traffic rules governing the wrong-way cyclist at intersections. If forced into the roadway, the left-side cyclist has more difficulty than the right-side cyclist, while in turning, the wrong-way cyclist is forced to cross paths with an oncoming car at a moment of neither's choosing. In addition wrong-way cyclists frequently collide with pedestrians and right-side cyclists.

COPING WITH INEXPERIENCE

Classroom preparation for motorcycle operators to enhance safety is considered. Motorcycle Safety Foundation and Kawasaki Learn to Ride courses are offered by local high schools and colleges. The "big brother/sister" concept is recommended to cope with inexperience. Interchange with an experienced driver will reveal common do's and dont's: do not borrow or lend; steer left to go right at speeds greater than 10 mph; allow front brakes to do most of the work; take railroad tracks at a direct angle; conduct daily maintenance and pre-ride checks; use the neutral gear at stoplights; do not ride "two-up" without experience; use protective clothing; watch for gravel or water in the roadway; be wary of crosswinds; get insurance; and "keep the shiny side up and the rubber side down".

BACK TO BASICS: TOOLS

Basic information to aid "backyard mechanics" in vehicle repair is presented, with emphasis on tools. Due to the economy, many consumers are becoming interested in doing their own repair work. Most vehicle maintenance is not difficult and requires only a little special knowledge and a modest investment in equipment. Adequate lighting and a workbench are two essentials of a work area. A pair of safety stands, jack stands, or ramps is also needed. Basic tools include a set of open-end combination wrenches, sockets and a socket wrench, a medium crescent (adjustable) wrench, screwdrivers, regular and needlenose pilers, vice-grip pliers, a feeler gauge, a spark-plug wrench, a 12-volt test lamp, and a rubber hammer.

A CRITIQUE OF THE THEORY FOR GUSSAC'S "LAG (AVALANCHE ACTIVATION OF COMBUSTION) PROCESS" ENGINE

The theory of the LAG process (Russian acronym translated into English as avalanche activation of combustion) is examined. Developed by Gussac, the LAG process uses a dual-chamber engine. The main chamber contains a fuel-lean mixture, and the smaller chamber contains a fuel-rich mixture. When mixture in the small chamber is ignited by a spark, it burns and ejects a jet of hot combustion products into the main chamber. Passage between the two chambers must be of the proper size and shape to optimize the process. Gussac claims that chemically active radicals are generated in the small chamber and are injected into the large one, thus reducing ignition temperature and induction period (i.e. increasing flame speed). His claim is based on Semenov's theory of branching chain reactions. Recent calculations, however, show that flame propagation does not depend on induction type chemistry. The flame produces enough radicals to achieve a steady state radical concentration ahead of the flame. Additional radicals from the prechamber would be superfluous and would raise the temperature only slightly as they are consumed. Alternative explanations for the improved engine performance claimed by Gussac are offered. Further research is recommended to explore these explanations rather than to examine ways of reducing induction time in the main chamber. Semenov's theory is reviewed in an appendix; it is shown that buildup of radical concentrations governs the induction period and that the rate of fuel consumption is determined by the steady-state radical concentration.

THE EFFECTIVENESS OF WRITTEN DRIVER KNOWLEDGE TESTS

As part of the requirements for a "partial temporary waiver of Highway Safety Program Standard No. 5" granted the State of Virginia, an experimental evaluation was made of several alternative approaches to the requirement that applicants for license renewal be tested on rules of the road at least once every four years. Members of the renewal population of drivers were randomly assigned to four study groups: a control group receiving no treatment; a group receiving only a driver's manual; a group receiving a manual and a test to be taken at home; and a group receiving a manual and requested to take a test in the Dept. of Motor Vehicles examining station when applying for license renewal. The subsequent driving performance of members of the four groups was monitored and data for accidents, major and minor convictions, accidents with associated convictions, and administrative actions under the Driver Improvement Program were tabulated at 6-, 12-, 18-, and 24-month intervals. For the two groups given a knowledge test, few statistically significant differences were found among those who passed, failed, or refused to take the test, none of which suggested the practicality of knowledge testing as an effective highway safety measure. It is therefore recommended that the temporary waiver of the requirement for reexaminations of knowledge of the rules of the road be made permanent, and that the Standard be amended to eliminate the requirement for such reexaminations.

DEPARTMENT OF ENERGY UNVEILS ADVANCED ELECTRIC CAR

The Electric Test Vehicle-One (ETV-1), developed as part of the Department of Energy's electric vehicle activities, is an advanced four-passenger subcompact vehicle. Although ETV-1 is a test car, not commercially available, it has been designed to be mass-produced for about $6,400 (1979 dollars) by 1985. The car's 10-year life cycle cost, including electricity for recharging, is estimated to be less than 18 cents per mile. Advanced features of the ETV-1 include: computerized control systems; low-cost high-current power transistor modules to control motor speed; integrated electronics that permit double use of the same electrical circuit to control both motor speed and battery recharging; regenerative braking that captures energy normally lost in braking for use in battery recharging; batteries with 25% higher energy and longer life than those available today; aerodynamic body design, reducing air resistance to 60% of presently available subcompact cars; and extensive use of lightweight materials to reduce overall weight. Computer performance projections indicate a 100-mile driving range at speeds up to 45 mph with two passengers. The ETV-1 can cruise at 55 mph, pass at 60 mph, accelerate from 0-30 mph in nine seconds, and climb a 5% one-mile grade at 50 mph. Eighteen improved lead acid batteries power the car. Engineering and technological efforts in building the car involved $7 million, but only 7% of this figure or about $500,000 went into actual vehicle fabrication.

HOW WILL DOWNSIZING AFFECT FATALITIES?

The impact of downsizing U.S. cars on motor vehicle fatalities in 1995 is projected. Crash-injury data from files maintained by the Hwy. Safety Res. Inst. at the Univ. of Mich. were applied to police-reported Texas accident data for 1975-1976. These statistics were then projected to the 1995 driver and vehicle population. The emphasis was on determining whether the 1995 fleet of smaller and lighter cars would contribute to more or fewer annual fatalities than a 1995 fleet mix of passenger cars with the size and weight of cars on U.S. roads in 1975. Findings showed that downsizing itself is a slightly negative factor, i.e., downsizing will increase the total annual number of motor vehicle fatalities in 1995 by about 6%. Several other factors, however, will reduce fatalities (roed and traffic signaling improvements, lower percentage of drivers under 25 years of age, passive restraint systems, and other vehicle design improvements) or increase fatalities (projected 25% increase in the number of licensed drivers and 27% increase in the number of passenger cars, likely increase in the average annual mileage per vehicle over the 1975 average of 9,635 miles per vehicle, higher percentage of occupants over 35 years of age, and smaller and lighter cars that decelerate more abruptly in collisions and subject occupants to higher injury-producing forces). Results of accident involvement analysis in Texas are detailed, and supporting data are provided.

CHILDSAFE GOES NATIONAL

The National Safety Council's Project Childsafe is described. Automobile crashes represent the number one child killer in the United States. Each year, more than 1,000 children under four years of age die in automobile accidents and thousands more are seriously injured. Most crashes occur during routine neighborhood driving, less than 30 miles from home, and at speeds of less than 30 mph. Project Childsafe was started in Wisconsin through sponsorship of the Wisconsin Hospital Association and the Wisconsin Dept. of Public Instruction. The first target group to receive instruction involved new mothers in hospitals. They learned about hazards of permitting young children to travel unrestrained in automobiles in their postnatal classes. The National Safety Council purchased Project Childsafe in 1978 and is mounting an intensive effort to promote it nationwide. The council hopes to encourage parents to use properly tested child restraints for all children under 40 pounds or under four years of age and to warn consumers that some restraints on the market are not crash-tested. The educational program consists of a slide-cassette presentation, a brochure, and a poster that comprise a ready-made community safety education program. Use of the program by hospitals, community groups, clinics, pharmacies, libraries, schools, day care centers, physicians' offices, automobile dealers and other merchants, and the news media is discussed.

STEERING CLEAR

The inspection and repair of power steering systems to minimize mechanical and safety problems is discussed. Most power steering problems present themselves in the form of a grinding sound when vehicle wheels are turned. A visual inspection of all power steering system components should include a test under pressure to pinpoint the precise origin of a leak. Belts should be adjusted to the correct tension. Power steering analyzers should be employed to detect hydraulic pressure problems. Low pressure can be caused by dirt in the flow control valve or can indicate damage caused by the abrasive action of dirt in the rotor or thrust plate. Pressure can be lost from internal leaks past rack piston rings, the valve body, worm seals, or a misaligned housing bore. Mechanical problems include seized tie rod ends and idler arms, binding steering column universal joints, and steering gear adjustments. Other common problems include stiff ball joints, worn constant velocity joints, bad wheel bearings, and loose bolts on the steering gears. The most important aspect of power steering gear-pump installation is the vehicle road test.

A LOOK BEHIND THE HEADLINES--TO SURVEY THE DOT (DEPARTMENT OF TRANSPORTATION) SURVEY

A survey of automobile repairs, sponsored by the Department of Transportation and conducted by the Johnson Environmental and Energy Center (JEEC), University of Alabama, is reported. JEEC efforts involve the inspection of all car-model years, pickup trucks, and vans since June 1976. One of its Auto Check programs, based on the inspection of 4,000 cars, revealed that: 25% of all repairs were unnecessary and represented 29 cents of every repair dollar. The unnecessary repair rate dropped to 13% when consumers were given detailed information about what needed to be fixed. Control arm pivots, brake disks or drums, and rear wheel seals had high unnecessary repair rates. Local car dealers who performed the most cost-effective repairs had a larger share of the repair business while chain stores with the lowest unnecessary repair rates had the largest business volume. The market share of chains and tire dealers increased with the use of "prescription forms" telling customers exactly what was wrong. Criteria used by the JEEC in setting up the study was examined (106 items on the Auto Check inspection form and the classification of repairs as required, recommended, optional, or unnecessary). The JEEC data sharply contrasted with the findings of the Department of Transportation's "undercover" investigation of auto repair practices and costs in 62 shops, nationwide. That survey found that 53 cents of every dollar spent on auto repair is wasted, and that the consumer has only a fifty percent chance of having a car repaired at the right price.

HOW TO CHECK AND REPLACE GASKETS AND SEALS

Replacement work for car gaskets and seals is explained. A gasket makes a seal between two metal surfaces to prevent fluid and/or pressure leaks. The main purpose of oil and grease seals is to protect bearings by minimizing lubricant loss and bearing contamination by dirt and water. According to one industrial source, safety requires greasing front-wheel bearings and installing new seals every 10,000 miles. This interval provides an ideal time for brake inspection. Installation procedures for front-wheel seals, gaskets in general, oil filter gaskets, thermostat gaskets, fuel pump gaskets, oil pan gaskets, and rocker arm (valve) covers are detailed. Illustrations are provided.

FUEL FOR THE FUHRER

Captured documents on the German synthetic fuel industry of World War II, with reference to the refining process for making "syncrude" fuel ready to use in motor vehicles, gives the United States a blueprint that can help accelerate development of our nation's coal-conversion process. The need for Germans to develop synthetic fuels was an economic one since the country has little natural petroleum. Coal liquefaction techniques won Bergius a Nobel Prize in 1931. In the Bergius process, coal is ground and mixed with heavy natural or synthetic oil (heavy synthetic oil is made as a byproduct during coal liquefaction). The next step is to push the coal-oil mixture (slurry) into reactors in which the coal liquefaction occurs. The combination of hydrogen, pressure, and temperature breaks down coal into a liquid, and what leaves reactors is synthetic crude oil. To make syncrude ready for use in motor vehicles requires a process similar to that for refining natural crude oil. A distillation process removes volatile components of syncrude. Vapor resulting from distillation is reacted with hydrogen to become liquid fuel. Blending raises the octane of synthetic fuel to meet needs of motor vehicle and aircraft engines. The Fischer-Tropsch process is used to liquefy coal that is low in nitrogen. Historical events in Germany's synthetic fuel development, including Hitler's four-year plan (1939-1942), are traced. Application of the German experience to U.S. energy plans is discussed.

GAS-SAVING GADGET...THAT WORKS

A throttle positioner is Douglas G. Noiles' way of getting mor
miles per gallon of gasoline from his car. Noiles, a mechanica
engineer for a surgical firm, primarily attributes decreased fue
economy for automatic transmission cars to the automatic trans
mission which requires high engine idling speeds when no
under load to operate properly with both transmission and ai
conditioner engaged. This condition requires a more ope
"closed throttle" than when the engine is idling, the transmis
sion is in neutral, and the air conditioner is off. The heart o
Noiles' throttle positioner is an ordinary distributor vacuun
advance. The engine chamber is fitted with a support bracket t
permit mounting of the vacuum advance on the antidieselin
solenoid. A hose connects the vacuum advance to a port in th
carburetor base. Manifold vacuum allows the advance to con
trol throttle valve opening. The Noiles throttle positioner i
effective in heavy-load, stop-go situations but does not improv
gas mileage for constant speed driving. To benefit most fron
the device, a car should have an automatic transmission, ai
conditioner, and antidieseling solenoid.

MAJOR BREAKTHROUGHS IN DETROIT

Four breakthrough applications of plastics in Detroit's 198
model cars are noted. Innovative concepts include a radicall
new window-regulator mechanism fabricated almost entirely c
plastics; an all-polycarbonate (PC) headlamp system; the fir
injection molded one-piece PC instrument panel, and the fir
reaction injection molding (RIM). Value analysis, design an
styling considerations, and the need to save weight provide th
rationale for these innovations. The trend in value analysis is t
bring increased competition among materials and processes, in
cluding renewed interest in structural foam. Reinforced an
otherwise toughened material grades are increasing in use wher
propylene is concerned. Operational, performance, cost, safety
and energy management aspects of innovations in Gener
Motors and Ford cars are detailed.

STRUCTURAL ADHESIVES BID FOR BIG PLASTICS-TO-PLASTICS BONDING JOBS

New formulations of structural adhesives are building c
second-generation formulations that offer fast cure, low exothe
mic heat, and good bond strength. Typical are National Starc
and Chemical Company's Hypac, a two-part acrylic system, an
Weldmaster 3, an interfacial cure system. Both are 100% rea
tive and form tenacious bonds between plastic materials or pla
tics and other substrates (wood, metal, ceramics, etc.). Oth
advances include Hughson Chemicals' Versilok 506 and 51
Versilok 506 is an acrylic structural adhesive for thermosets ar
thermoplastics. The no-mix Versilok 510 system offers he
resistance to 250 degrees F and cures to handling strength

seven minutes at room temperature. The new Futurethane 21 family of urethane adhesives from H.B. Fuller Co. combines speed, flexibility, and high strength for bonding polycarbonate, polyvinyl chloride, polysulfone, treated propylene, and reinforced phenolics. Goodyear Tire and Rubber Co. has one-component urethanes under development. Structural urethanes of Ren Plastics are reported to have good cold and moisture resistance, fast cure, and instant thixotropy. Advantages of new epoxies (Armstrong Products and 3-M) are variable viscosity and flexibility, room temperature or elevated temperature cure, and ability to bond dissimilar substrates. Hot melts, pressure sensitives, and cyanoacrylates are beginning to find new industrial applications, although the relative scarcity of high-speed equipment limits large-scale applications of structural adhesives in industry at present.

HEAD INJURY STUDIES. 1978 RESEARCH REPORT ON AUTOMOBILE SAFETY STANDARDS. SUMMARY

As a measure to reduce casualties suffered in automobile accidents, this research attempts to clarify the relation between impact and injury when humans are subjected to impact. Since the major site of injury is the head, determining the relation between impact and injury would provide useful data in formulating automobile safety standards. Research covered the 1976-1978 period and involved experiments on the heads of monkeys. Impact was delivered to the entire head surface through a cranial plaster mask prepared for each subject. Cranial rotational impact and occipital impact were studied. Engineering measurement and medical examination data were obtained. A correlation between impact upon the unrestrained head and the degree of encephalic contusion was determined. Brain contusions were found in 56% of monkey brains subjected to autopsies when brain concussions were evident. Subarachnoid hemorrhaging was virtually absent at the extent clinically evident in desiccated human skulls. Compared with humans, brain concussions of monkeys were slight. Fracture limits were established for human skulls using desiccated human skulls under both static compression and impact tests. A safety limit curve for human skull impact is proposed.

HIGHWAY ACCIDENT REPORT. CROSS-MEDIAN, MULTIPLE VEHICLE COLLISION AND FIRE, STATE ROUTE 2, NEAR CLEVELAND, OHIO, MAY 6, 1979

A multi-vehicle accident occurred on State Route 2, Willowick, Ohio on 6 May 1979. An eastbound 1976 Dodge van crossed the median and collided with a westbound 1971 Ford LTD. The van then proceeded a short distance and collided with a westbound 1976 Oldsmobile. In this collision the van and Oldsmobile were engulfed in flames from gasoline spilled from a ruptured fuel tank. Five of the six occupants in the Ford were killed instantly; the sixth died on 13 May 1979. The van driver was ejected from his vehicle and injured seriously; the two occupants of the Oldsmobile escaped with minor injuries. The National Transportation Safety Board determined that the probable cause of the accident was the loss of control by the driver of the van for unknown reasons. Contributing to the fatal injuries of the occupants of the Ford was their failure to wear the available occupant restraints. It is recommended that median barriers be installed at the scene of the accident and at other locations with an adverse history of across-the-median accidents. It is also recommended that development of fuel tank integrity standards be expedited and that testing be conducted with vehicles in all conceivable impact attitudes.

CHARACTERISTICS OF URBAN TRANSPORTATION SYSTEMS. A HANDBOOK FOR TRANSPORTATION PLANNERS. FINAL REPORT

In an update of earlier reports under the same title, a handbook is provided for use by transportation planners and urban specialists for estimating system parameters for conventional transportation technology. Three modes are evaluated: rail transit, local bus and bus rapid transit, and highway systems. Each mode contains an assessment of seven selected supply parameters: speed, capacity, operating cost, energy consumption, pollutant emissions, capital costs, and accident frequency. These parameters are organized as proxy variables in describing the characteristics of each transport mode. Each mode is discussed in an Appendix section in which these parameters are evaluated in further detail and for particular geographic areas. Two additional Appendix sections contain all references used in the tables/figures, as well as a general bibliography.

WHICH ALCOHOL FUEL FOR BRASIL--METHANOL OR ETHANOL?

An updated account is presented of the achievements of the Programa Nacional do Alcool-ProAlcool (Brazilian National Alcohol Prog.), and of the recently proposed program to extract methanol from wood. The ProAlcool project is an ongoing Federal program established in Nov 1975 to promote increased production of ethanol fuel via fermentation. Addition of 20% anhydrous ethanol by volume to automotive gasoline is now practiced nationwide without vehicle modification, and experiments are being conducted on the substitution of methanol and alcohol for diesel fuel. Investment subsidies are provided by the Brazilian government for expansion and revamping of distillaries and ethanol production, which was nearly 1.5 million cu m in 1977, a 100% increase over 1976. Estimates for the harvest year 1978-1979 indicate ethanol production of 2.5 million cu m, and the 1979-1980 forecast calls for 3.8 million cu m. A program for introducing several 2000 ton/day methanol plants based on gasification of wood (eucalyptus) has been proposed by CESP-Sao Paulo State Energy Utility. Methanol could potentially be recovered as a byproduct in the production of charcoal for blast furnaces. The production, utilization, and process considerations of ethanol and methanol are discussed. Despite high capital investments and higher initial costs, alcohol fuels show promise for oil-scarce countries such as Brazil, which have abundant land, water, and sunshine. New energy sources are needed to help reduce Brazil's heavy dependency on oil (42% of current energy demand) of which 82% is imported, resulting in a severe trade deficit. Important social benefits from increased alcohol production include creation of jobs in rural areas, improved income distribution, and a more balanced development of the country.

IMPROVING OCTANE VALUES OF UNLEADED GASOLINE VIA GASOHOL

A series of quantitative utility factors is developed to demonstrate that the use of alcohol can improve the octane rating of unleaded gasoline and reduce the need for the U.S. to import more oil. The addition of ethanol to gasoline (to make gasohol) improves the octane rating by two to four points. Comparative calculations show that one BTU of ethanol octane-boosting additive replaces 3.6 BTU'S of petroleum and that 6% more crude oil is required to produce high octane unleaded gasoline than regular gasoline. Although ethanol has 2/3 of the BTU value of
gasoline, gasohol offers a 5.3% to 6.1% improvement in fu
economy. Claims that ethanol production requires two BTU's o
energy input for each BTU of output are shown to be limited t
analyses of the production stage, not of end use of the ethano
produced. These claims also fail to consider the use of nonpetro
leum inputs during methanol production. In all probability, us
of a 10% ethanol/gasoline mixture will save at least two units o
petroleum or gas energy for each unit that it replaces.

PREDICTION OF VEHICLE PERFORMANCE AND ITS SENSITIVITY TO COMPONENT IMPROVEMENTS: APPLICATION TO ELECTRIC AND H2 (HYDROGEN)--FUELED VEHICLES

Simple, algebraic equations are used to relate vehicle mass (WT
and energy consumption (C) to parameters describing electri
and hydrogen (H2)-fueled vehicles. By differentiation, the sens
tivity of WT and C to component improvements is determine
and used to formulate a rational research and development (
and D) investment policy. For H2-fueled and electric vehicle
R and D investment in improving vehicle energy-storage d
vices is predicted to produce greater decreases in WT and
than investment in the powertrain. Using a published forecast
component characteristics, WT and C for both kinds of vehicl
are projected into future time frames. Between 1985 and 1990
range of 150 km is projected, increasing by the mid- 1990's
250 km. The results show that the lead-acid battery, possessi
the most optimistic characteristics forecast, does not result in
practical electrical vehicle (EV) for any of the missions (Com
muter Car Cycle and Scott Cycle for both ranges), nor does th
nickel/iron battery for the 250 km Scott Cycle mission. Gene
ally, the EV'S exhibit greater WT/WPL (energy-storage-devic
mass) than the metallic hydride vehicles, but the higher energ
efficiency of EV's can result in relatively lower values of C
WPL. Appended is an analysis of the beneficial impact of fl
wheel transmissions on vehicle WT and C.

REGENERATIVE FLYWHEEL ENERGY STORAGE SYSTEM

The current status is described of a program to develop a
evaluate a regenerative flywheel energy storage system for
battery/flywheel electric vehicle (EV) in the 3000 lb cla
Planned laboratory tests will simulate this EV operation ov
the SAE J227a Schedule D driving cycle. The range improv
ment attributed to the flywheel will be established; it is proje

ed to be from 40% to 50% greater than that of an all-battery vehicle when used in a repetitive, start-stop driving cycle. The flywheel energy storage system will consist of a solid rotor, synchronous inductor-type flywheel drive machine electrically coupled to a DC battery electric propulsion system through a load commutated inverter. The motor/alternator unit is coupled mechanically to a small, steel flywheel which provides a portion of the vehicle's accelerating energy and regenerates the vehicle's braking energy. The laboratory simulation of the EV propulsion system will include a 108 volt lead-acid battery bank, a separately excited DC propulsion motor coupled to a flywheel which simulates the vehicle's inertia, and the flywheel energy storage system comprised of the motor/flywheel unit, the load commutated inverter, and its control.

A THERMAL ENERGY STORAGE SYSTEM FOR A STIRLING ENGINE POWERED HIGHWAY VEHICLE

The conceptual design of an automotive propulsion, thermal energy storage (TES) system has been developed that utilizes the sensible and latent heat of fusion of a molten fluoride salt. Electromechanically pumped potassium serves in the vapor-liquid heat transport system, and high-performance nonmetallic insulation is utilized to minimize energy loss. A vehicle range of over 160 km (100 mi) can be achieved with a 500-kg system, and peak power rates in excess of 200 KW can be delivered. Life cycle costs of the TES system with electrical energy recharge are projected to be 10.6 to 11.1 cents/mi; costs of 9.9 to 10.5 cents/mi might be possible with natural gas recharge. Recharge time constraints for either natural gas or electric recharge will probably prevent TES system vehicles from replacing conventional internal combustion engine vehicles. Psychological effects related to the safety of molten salt TES systems (possibility of fire during accidental potassium release) and necessary institutional changes in crash control and removal procedures may present significant barriers to public acceptance. It is suggested that 1/2 or 2/3 scale (50 to 66 kWh) version of the present system be selected for demonstration.

THE 1978 STATE OF THE ART OF IN-USE ELECTRIC AND HYBRID VEHICLES

The second-year effort to assess the state of the art of in-use electric and hybrid vehicles (EHV's) is summarized. Included are the results of extensive contacts with, or site visits to, users and manufacturers of these vehicles, as well as battery and component manufacturers and administering agencies in the U.S., England, Germany, France, and Japan. The only long-term, cost-effective fleet operation of EV's (electric vehicle) worldwide is the milk delivery system in England. Japan is the only country with hybrid vehicles in daily commercial use. The EV in the U.S. has captured the interest and involvement of the major battery manufacturers and component suppliers, but has found only marginal interest from the major automobile and truck manufacturers. Major automakers outside the U.S. have shown a more active interest in the EV. The only large-scale EV fleet in the U.S., that of the Postal Service, continues to operate satisfactorily. The light-duty truck (delivery van) in fleet operations and specific duty cycles is the most common EV application. Fleet operation appears to be the most appropriate means for introducing this new vehicle technology. Successful introduction and effective utilization of EV's require a mature infrastructure: electric power generation, transmission, and distribution systems; charging or battery transfer facilities; maintenance facilities; vehicle dealer networks; replacement parts; vehicle maintenance and repair procedure documentation. Modular design, failure warning, and back-up systems can do much to permit "limp-home" operation. Purpose-designing offers the highest probability of successful EV performance. Limited performance capabilities and high cost are the major barriers to sizable market penetration.

CURRENT DEVELOPMENT ACTIVITIES ON ELECTRIC VEHICLES IN EUROPE

European research and development (R and D) activities concerning electric vehicles (EV's) are reviewed country by country. England is the only country in Europe with a living tradition in EV's, i.e. the "milk float" of about 50,000 vehicles which distribute dairy products in urban areas. The Electric Vehicle Devel. Group of England was formed in 1978 to promote the establishment of a diverse electric road transport system. The Energy Res. Group of the Open Univ. Milton Keynes is presently studying the systems effects associated with widespread use of EV's. National Carriers Ltd., in a consortium with Chrysler (U.K.) Ltd. and Chloride Technical Ltd., introduced the Silent Karrier electric delivery vehicle in 1976. The British government supported its battery technology, and the Greater London Council is sponsoring a large-scale, three-year trial of the Silent Karrier and vehicles designed by Lucas and Crompton Parkinson. Joseph Lucas Ltd. is conducting a program to develop lightweight traction batteries as well as complete electrical drive systems. The company has put into service Post Office vehicles, a Pullman Personnel Carrier, a Midi bus, and a taxi cab. In the Federal Republic of Germany, most of the money invested since 1974 by government and private sources for electric and hybrid vehicle R and D has been used to develop delivery vans and buses by a consortium of Volkswagen, Daimler Benz, MAN, Bosch, Siemens, and Varta. In 1975, GIVE (Electric Vehicles Interministerial Com.) was created in France to initiate the development of electric commercial vehicles. ENEL, the Italian National Electric Board, has in recent years launched an extensive R and D, and demonstration program for EV's. In Belgium, the Free Univ. of Brussels is conducting EV battery studies. Eindhooven Univ. of Technology (Holland) is studying lead-acid batteries and is working on an electric car project. Switzerland offers a four-seater electric road vehicle, the Carville (Electrona Ltd.). In Sweden, main efforts have been in nickel-iron and nickel-zinc battery development. SAAB has made several prototype EV's and a new company, SETU, was established to develop large-fleet EV's.

THE DESIGN OF AN ENERGY EFFICIENT HIGH PERFORMANCE HYBRID-ELECTRIC VEHICLE

To decrease the amount of gasoline consumed by automobiles, a gasoline-electric hybrid vehicle has been designed which uses electrical energy for city driving and gasoline for highway cruising or for city driving after the batteries have been discharged. To minimize energy consumption while retaining performance equal to or better than that of current gasoline vehicles, the car is propelled by energy stored in the flywheel. Energy can be put back into the flywheel by regenerative braking. The electric motor controls are extremely simple since the motor is only used to accelerate the flywheel at full current or when it is shut off. The internal combustion engine may also be used to charge the flywheel, but it is never used to recharge the batteries as it is much more efficient to put all of its energy into the flywheel. The batteries, electric motor, and flywheel are built into one discrete unit. Since these components are not needed for highway cruise, this unit can be removed to lighten the vehicle and provide room for luggage. This vehicle was designed for near-term production, emphasizing simplicity. Any future improvements in battery technology will increase the appeal of this concept.

APPLICATIONS OF FUEL CELLS IN TRANSPORTATION

Technical and economic evaluations of the potential use of fuel cells to power four vehicle types are summarized: city bus, highway bus, delivery van, and consumer car. The phosphoric acid fuel cell was used as the baseline (fuel cell and reformer data supplied by Energy Res. Corp.). Two cell sizes (15 kW and 60 kW) and two fuel options (methanol and propane) were utilized. The results of analysis of the four target vehicles strongly suggest the feasibility of the fuel cell vehicle in the 1990's. No fuel cell, battery, motor, or vehicle aerodynamic performance improvements were projected in making this assessment. Technical feasibility was demonstrated in each vehicle. Economic viability was more difficult to prove because of the scarcity of uniform vehicular performance, duty cycle, and economic data, and the lack of experience with fuel cells in the vehicular environment. Since conservative rather than optimistic estimates were used in the analysis, prediction of first-order economic viability in the 1990's seems justified.

THE EFFECT OF MECHANICAL ENERGY STORAGE SYSTEMS ON THE CHARACTERISTICS OF ELECTRIC VEHICLES

Batteries for electric vehicle (EV) propulsion can be develope to effect tradeoffs between short-term peak power capabilit and energy storage capacity. Such batteries in combination wit a mechanical energy storage device can optimize both EV power and range capability. Equations are derived for determining the vehicle mass fraction of the mechanical energy storag system that is required to achieve a vehicle mass saving o increase in range. The extent to which mechanical energy storage systems can improve EV performance depends upon th battery type and the vehicle power/mass requirements.

ADVANCED FLYWHEEL ENERGY STORAGE UNIT FOR A HIGH POWER ENERGY SOURCE FOR VEHICULAR USE

A one-year program is described involving the design, fabrication, and experimental determination of the performance of an advanced, hermetically-sealed energy storage unit (ESU) that has been sized for a typical 3000-lb curb weight vehicle. The program is designed to provide decision-making information regarding the benefits of a mechanical energy storage device as it applies to vehicle fuel consumption or range. The benefits must be great enough to reduce the life-cycle cost of the flywheel propulsion system below that of a conventional propulsion system. The total weight of the ESU is 80 lb, corresponding to a total specific energy of 3.16 w-hr/lb and a specific power of 569 w/lb. The ESU design utilizes a dual-pressure chamber concept wherein a composite material flywheel rotates within a cavity under about 1 micron pressure during operation while the remainder of the unit is pressurized to 2 torr. This pressure differential is provided by a molecular pump. When the unit is at rest, the internal pressure in both cavities equalizes at approximately 1 torr. The transfer of energy in and out of the unit is accomplished by an electrical induction machine coupled directly to the flywheel. The maximum power transfer is 45 kw, which is available at all operating speeds between 21,000 and 42,000 rpm. The slip control method used to modulate the power is based on comparing electrical machine speed, inverter frequency, and commanded power. Three main categories of tests in the ESU development program are performance (spin-down losses), proof of design, and environmental.

HS-027 237

A HIGH EFFICIENCY CONTROLLED SLIP INDUCTION MOTOR DRIVE FOR ELECTRIC VEHICLES

Ongoing research is described in the development of an advanced electric vehicle induction motor drive system consisting of a three phase inverter and an induction motor. Since this drive is operated in a controlled slip mode (variable frequency, variable voltage) it is capable of supplying breakdown torque at stall without having to sacrifice low slip characteristics at normal operation. As the machine is operated at low slip over the entire speed range, a major improvement in efficiency is realized. Regenerative braking is also easily obtained by changing the sign of the slip. Despite the increased controller complexity, a significant potential exists for the induction machine/controller combination to result in an overall lower cost system compared to DC systems. This combination offers maintenance-free operation. Inasmuch as the trend of rapid reduction in power semiconductor costs is expected to continue, additional widening of the potential advantage of the induction/controller approach is expected.

WHEEL HUB MOTORS APPLIED TO ELECTRIC VEHICLE PROPULSION

The Power Wheel, which is uniquely configured with a combination of axially aligned magnetic pole pieces, is described. It is designed to minimize the frictional losses normally encountered with moving parts such as bearings, gears, and sliding surfaces, and to recover through the regeneration process some of the kinetic energy usually dissipated in stopping a vehicle by frictional braking. The magnetic gaps lie in two parallel planes perpendicular to the rotation axis. The 12 stationary electromagnet poles used in the 15-in wheel hub design for the automobile are wound on high-permeability, silicon C-cores which are mounted back to back on radial support arms of nonmagnetic stainless steel. Magnetic flux paths are split into two balanced fields which interact with corresponding pairs of permanent magnets. Cogging or stepping is virtually undetectable because the brushless commutation scheme produces 132 distinct switching intervals for each revolution of the wheel. Variable-speed operation of the wheel hub motor is accomplished using a cycloinverter. The high-frequency component of the cycloinverter waveform is generated by an inverter external to the wheel. This fundamental, low-frequency component is derived from the output of Hall-effect devices and produces the synchronous torque. Rotational torque is achieved by directing current through each of six pairs of independently controlled electromagnet poles in order to produce a magnetic field that attracts the closest approaching permanent magnets and repels the departing adjacent permanent magnets. A promising application of the power wheel concept is the Sky Shuttle, an urban mass transit vehicle capable of carrying 160 passengers along a set of bridge-like, catenary-supported cables. Duluth, Minn. may be the first city to establish a pilot stretch of second-generation Sky Shuttle trains.

AN ELECTRIC VEHICLE DRIVE CONCEPT USING A CENTRIFUGAL CLUTCH

An electric vehicle drive concept is described which uses a separately excited DC motor controlled only by a transistor field control, a centrifugal clutch, and a transmission with a choice of three gear ratios, thus offering automatic driving behavior and high efficiency. Performance data (hill climbing ability, maximum speed, acceleration) are derived from motor and clutch characteristics of a Volkswagen (VW) Electric Pick Up equipped with the drive system, and are compared with test results. Dynamic driving behavior of the test vehicle is diagrammed and discussed. With a maximum speed of 77 kph and a hill climbing ability of 22% at 12 kph, the prototype test vehicle meets or exceeds the performance of a VW Van with fully electronic control except for acceleration, which is 21 seconds from 0 to 50 kph. The VW Van with fully electronic control has a maximum speed of 70 kph, a hill climbing ability of 14%, and acceleration from 0 to 50 kph in 13 seconds. A problem with the new drive system is clutch judder, which sometimes occurs during the slip mode operation of the centrifugal plate clutch.

THE DEPARTMENT OF ENERGY ELECTRIC VEHICLE BATTERY PROGRAM: AN OVERVIEW

Funding levels, performance goals, and battery systems under development are described for the Dept. of Energy's (DOE) electric vehicle (EV) battery program which includes near-term battery development and advanced battery research and development. The near-term segment was established to support the EV demonstrations mandated by the Electric and Hybrid Vehicle Research, Development, and Demonstration Act of 1976 (EHV Act). For EHV Act vehicles, the improved battery technology will be available no later than 1984. This near-term battery program involves the development and engineering design of three types of full-size vehicle batteries (20 to 30 kWh): nickel/zinc, nickel/iron, and improved lead-acid. The advanced battery technology, involving more energetic electrochemical systems and higher performance goals, is expected to be available for vehicles built in the late 1980's and beyond. These advanced batteries should enable EV manufacturers to produce vehicles capable of 150 mi range or more, with acceleration and cruise speeds virtually equal to heat engine vehicles. Four types of advanced batteries receiving DOE support are lithium/metal sulfide, sodium/sulfur, zinc/chlorine, and metal/air (e.g. iron/air, aluminum/air). Support for EV batteries is also provided through other elements of DOE's broadly based Electrochemical Systems program. This includes research on fundamental electrochemical problems of selected EV battery couples, development of improved cell components and battery system components, studies relating to battery/vehicle integration and battery environmental and safety issues, and exploratory investigation of new EV battery candidates.

A COMPARISON OF METAL-AIR BATTERIES FOR ELECTRIC VEHICLE PROPULSION

The characteristics and properties of four metal-air battery systems being considered for future use in commuter electric vehicles (EV's) are briefly described, and a comparison is made of their expected performance, use conditions and operating costs. The anode materials are lithium (Li), aluminum (Al), zinc (Zn), and iron (Fe). For an Al-air (mechanically rechargeable) system now being developed, projected performance for specific energy content (and hence range) is superior to that projected for either Zn-air or Fe-air. An Fe-air secondary battery equipped with a bifunctional air electrode is expected to have peak power comparable to that of the Al-air system. The tradeoff for these two systems occurs between the more extended range for Al-air and the lower cost (ownership and operation) and ease of recharging (maintenance) for Fe-air. An imaginative design approach has allowed demonstration of a slurry Zn-air system which avoids the problems usually associated with the Zn plate electrode, but projected performance and cost estimates for this system indicate its inferiority to Fe-air and Al-air. While Li-air is in a very early development stage, Fe-air secondary batteries have already been used in commuter EV's.

EVALUATION OF BATTERY PERFORMANCE USING COMPUTER CONTROLLED TEST EQUIPMENT

A series of charges and discharges were performed at widely varying currents and over a range of temperatures on large groups of lead-acid batteries as part of a program to improve the state of the art of the electric vehicle battery. Thirty-two design variables involving 96 batteries were studied. Discharges were performed at constant current values of 10, 40, 60, 80, 150, and 250 amperes, at 25 degrees C, 40 degrees C, and 0 degrees C. The thermal and electrical performances of individual plate groups, individual cells, and complete batteries were recorded on magnetic tape. These data were subsequently reduced to graphic and tabular form for analysis. The design of the test equipment, its operational modes, and typical data output is discussed in terms of both battery and computer technology. Design and construction data (e.g. active material weights, component composition, battery specific gravity, battery weight) were also computerized. A preliminary analysis of the test data indicated that the techniques are adequate to handle the complexities of large-scale testing of the numerous different designs of lead-acid batteries normally tested as part of a major design and development program. The use of separate microprocessors for control and recording coupled with immediate data storage on magnetic tape reduces the probability of losing irretrievable data. The use of redundant components usually limits failures, provides interchangeability of parts, reduces maintenance of spare components, and speeds isolation and repair of malfunctions.

ADVANCES IN THE DEVELOPMENT OF LI-AL/FES (LITHIUM-ALUMINUM/IRON SULFIDE) CELLS FOR ELECTRIC-AUTOMOBILE BATTERIES

The battery cells currently under development by Argonne National Lab.'s Lithium/Metal Sulfide Battery Prog. consist of Li-Al (lithium-aluminum) negative electrodes, FeS (iron sulfide) positive electrodes, a separator to provide electrical isolation of the electrodes, and molten lithium chloride-potassium chloride electrolyte. Most cells fabricated until recently have been of a prismatic, bicell design with a central positive electrode and two facing negative electrodes. Three types of separators have been used: BN fabric (Carborundum Corp.) with ceramic cloth (usually Zr02 (zirconium oxide)), BN felt, and Mg0 (magnesium oxide) powder. To achieve Mark II Battery performance goals modeling studies using the bicell design have indicated the need to develop and characterize the multiplate cell. A baseline multiplate cell having three positive electrodes, and four facing negative electrodes has recently been developed for evaluating alternative electrode separators. The assembly and operation of two of these multiplate cells and a number of bicells indicate that both BN felt and Mg0 powder show potential as suitable separators and substitutes for the more costly BN-Zr02 fabric combination. The performance of a bicell containing BN felt was improved by the use of a multiplate configuration. The multiplate cell achieved a 13% improvement in specific energy and a 50% improvement in specific power. A multiplate cell with Mg0-powder separator indicates similar performance improvement.

A CHARGING SYSTEM FOR THE LI-AL/FES (LITHIUM-ALUMINUM/IRON SULFIDE) ELECTRIC VEHICLE BATTERY

A proof-of-concept charging system for Li-Al/FeS (lithium-aluminum/iron sulfide) electric vehicle batteries of up to six cells have been built as part of Argonne National Lab.'s Lithium/Metal Sulfide Battery Prog. The system employs a unique current-controlled operating scheme by which the charge current is automatically adjusted throughout the charge cycle to ensure that the terminal voltage of each series-connected cell in the battery system remains at or below a predetermined safe limit level. The charger/equalizer system consists of three basic parts: the main charger, the individual cell monitor/shunt (M/S) electronic circuit modules, and the system control unit. Tests have been performed on both Li-Al/FeS and lead-acid batteries. Accurate and reliable operation has been achieved at various bulk and equalization charging rates and over a wide range of cell voltage limit levels. A 40-cell charger/equalizer system is to be fabricated for testing with a 48-V, 26-kWh, Li-Al/FeS battery. The charger/equalizer system may offer the following advantages to other battery system types: reduced gas generation, reduced water consumption, cleaner battery containers, reduced maintenance, and increased battery life. Cost-effective charging systems for lithium/metal sulfide batteries are expected when manufacturing volumes justify single integrated circuit packaging of the cell M/S modules.

MULTI-FOIL INSULATION CONTAINER FOR ELECTRICAL VEHICLE APPLICATION OF A LITHIUM-ALUMINUM/METAL SULFIDE BATTERY

A MULTI-FOIL insulation container has been developed for a 20-kWh lithium-aluminum/metal sulfide battery which has an operating temperature around 450 degrees C. In order to provide the maximum usable space in an electric vehicle, a rectangular configuration was selected. The enclosure consists of two nested corrugated boxes built of 0.031-in thick Inconel 718 (an age-hardening nickel-based alloy), with interior dimensions of 15.72 in x 9.80 in x 58 in and exterior dimensions of 18.77 in x 12.85 in x 60 in. The mass of the vacuum enclosure is 70 kg. The measured heat losses through the Prototype I insulation container are 100 W at 400 degrees C and 160 W at 475 degrees C. These excessive losses, almost twice the calculated values, seem to be the result of the tight compression of the MULTI-FOIL insulation at the rear walls of the enclosures, due to deflection of the rear panels of inner and outer boxes when the foil compartment was evacuated. If the design constraints are not significantly relaxed, the cost of a rectangular container for vacuum foil insulation is unlikely to be commercially viable unless an insulation can be developed that is load-bearing and that has an acceptable heat loss. The present nonload-bearing insulation will probably be economical only if it is used in a cylindrical container.

MODELING OF ZINC-CHLORIDE BATTERIES FOR ELECTRIC VEHICLES

The fundamental operation of the zinc chloride battery system is explained, and information is provided on the first commercial battery of this type for electric vehicle (EV) propulsion (components, design points, energy flow diagram, projected selling price). A safety study for the chlorine hydrate battery for EV applications is cited. The only potential safety hazard is chlorine release. Equations are used to describe the sensitivity of battery weight and battery volume to delivered energy and sustained power. Using the battery equations and data on the required weight of the vehicle mechanical structure, battery/electric van combinations matched to a desired payload (1/2-ton, 3/4-ton, and 1-ton) and vehicle mission (50 mi, 100 mi, and 150 mi on the SAE J227a(D) cycle) are presented for a selected vehicle design. The approximate selling price of the batteries is tabulated for various payload and range combinations.

CRYOGENIC HYDROGEN STORAGE AND REFUELING FOR AUTOMOBILES

The construction, filling procedure, pressurization, and safety aspects are outlined for two fuel tanks for liquid hydrogen (LH2) which were specially developed for automobile applications. A stainless steel tank has a capacity of 120 liters; an aluminum tank can hold 150 liters of LH2. The design and operation of a semiautomatic "filling station" for LH2 are described. The refueling unit was designed and constructed to show how LH2-fueled vehicles can be refueled simply and safely by untrained persons. The unit has two lines, one for LH2 and the other for gaseous ventilation from the car fuel tank. Pressurized LH2 (about 2 bar) coming from a main storage vessel passes down the fill line through a cryogenic solenoid valve (CSV) and a one-way valve, into the vehicle tank. Gaseous hydrogen ventilation takes place by the vent line, passing a one-way valve, a CSV, and back to the recovery system. The filling procedure requires only the pressing of two buttons and three manual steps: connection of the twin-hose plug and the tank valves, opening of the tank valves, and closing of the tank valves and removal of the twin hoses. A refueling time of 5 minutes for a 120 liter tank has been demonstrated for this "self-service gas station".

Versuchsanstalt fur Luft- und Raumfahrt e.V., DFVLR (Stut
gart, Federal Republic of Germany). Estimated containe
system production cost information was provided by sever
cryogenic vessel manufacturers in the U.S. A unique, sem
automatic LH2 "service station" developed in Germany is d
scribed (see also HS-027 247). A general assessment is given
the state of technology of vehicle hydrogen containers an
associated systems, including the identification of importa
"pacing items" deserving initial attention in prospective researc
and development activities. It is concluded that compared
other available options for hydrogen storage in highway veh
cles, the cryogenic liquid approach may stand alone in feasib
ity. Although not presently being actively pursued in the U.S
as are metal hydrides, the LH2 approach can probably
viewed as the "standard of comparison" among the alternative

CURRENT FREE-PISTON STIRLING ENGINE TECHNOLOGY AND APPLICATIONS

Technology levels and potential applications of free-piston St
ling engines (FPSE) being developed by Mechanical Techn
ogy's Stirling Engine Prog. are discussed. Three advanc
engine configurations are presently in the hardware phase
development. Concurrent linear generator development wo
has resulted in substantial improvement in the efficiency a
power output of these machines. A dedicated technical effort
being directed to achieve performance and reliability required
make the FPSE a major competitor with internal combusti
engines. Four development programs are aimed at establishing
family of power systems covering a market size from 1 KWe
15 KWe: 1 KWe fossil-fueled stationary electric generator,
KWe fossil-fueled heat pump, 5 KWe fossil-fueled hybrid el
tric vehicle propulsion system, and 15 KWe advanced so
engine generator. Application of the FPSE to smaller pow
sizes for cryogenic cooler applications has also been address
Combined with gas bearing technology, a hermetic system
high efficiency and long life can be an attractive alternative
present cooler configurations. It is believed that the FPSE
provide significant economic savings as well as multi-fuel ut
zation, low noise and low emissions. The prime applicat
areas for this engine are electric power generation for station
and hybrid propulsion systems, and residential and light co
mercial heat pump markets.

A STIRLING ENGINE POWERED TOTAL ENERGY SYSTEM: RECREATIONAL VEHICLE APPLICATION

A Total Energy System (TES) has been developed for recreational vehicle (RV) applications where the unique features of a new Stirling cycle engine enhance user comfort, convenience, and safety. Two companies, Thetford Corp. (U.S. company involved in recreation industry) and FFV (Swedish industrial group which developed a commercial Stirling engine), developed the TES in 1970, merging in 1977 to form Stirling Power Systems Corp. (SPS). Prior to TES development, functional components for heating, air conditioning, cooking, and refrigeration were available for RV's but not as an integrated system. The integration of components, including the FFV Stirling Engine or Stirling Power Pack (SPP), was accomplished in cooperation with Winnebago Industries, a leading motor home manufacturer. The TES is quieter, more efficient, safer, and less polluting because of its unique design and use of the Stirling powerplant. It is composed of a number of convenient modules: SPP, roof unit, heating system, electrical control center, battery charger/inverter, and control panel.

NITROSAMINES IN NEW AUTOMOBILES

Thirty-eight 1979 model year automobiles were tested in the Boston, Mass., area to evaluate interior levels of airborne nitrosamine pollutants. Gas chromatographic analysis was carried out using an isothermal gas chromatograph (Thermo Electro Model 661) interfaced to a TEA analyzer (Thermo Electro Model 502LC). Except for one vehicle, all automobiles were new and were tested at car dealerships. Volatile nitrosamines, including N-nitrosodimethylamine (NDMA), N-nitrosomorpholine (NMOR), N-nitrosodiethylamine (NDEA), and possibly N-nitrosodibutylamine (NDBA), were present as airborne pollutants. Levels ranged from 0.07-0.83 micrograms per cubic meter for NDMA, 0.07-2.5 for NMOR, 0.04-0.39 for NDEA, and trace levels for NDBA. With the engine running, nitrosamine levels on a two-hour sample taken in the rear seat were reduced fivefold to tenfold, compared with the engine being off. This implies that, for late model cars, human exposure to nitrosamines is probably limited to the first few minutes of each trip. Nitrosamine exposure to humans in new cars is similar to that from beer and bacon.

OPERATION C.A.R.E. (COMBINED ACCIDENT REDUCTION EFFORT)

Operation CARE (combined accident reduction effort) was initiated during the 1977 Memorial Day weekend as a coordinated effort by State law enforcement agencies to assure compliance with the 55-mph speed limit, prevent traffic fatalities, reduce automobile accidents, and lessen personal injuries. In preplanning sessions for the holiday, two State police sergeants from Indiana and Michigan determined that speed limit visibility and enforcement should be consistent as motorists left one State and entered another. Thirty-six States participated in a 1978 meeting to lay plans for a national cooperative effort. Operation CARE has the primary goal of accident prevention during the Memorial Day, Independence Day, and Labor Day holiday weekends. A unique feature of the program is State management. The Federal Government does not mandate or control the program. The Department of Transportation estimates that enforcement of the 55-mph speed limit over the next 10 years can save 31,900 lives, forestall 414,000 injurious accidents, and save 30 billion gallons of gasoline.

A COMPENDIUM OF FEDERAL TRANSPORTATION POLICIES AND PROGRAMS

A description and summary are presented of Federal transportation policies and programs as enunciated by the executive, congressionl, and judicial branches. The purpose of the report is to provide a basic framework of status quo Federal transportation guidelines and actions, so that proposed changes can be analyzed within the context of this existing framework. A narrative description is given of the sources of Federal policies and programs for the intercity, urban, rural and international markets, with attention to the gaps and conflicts in these policies and programs. It is concluded that, instead of a unified national transportation policy, the U.S. has an assortment of policies and programs which have been developed in an ad hoc fashion. These are marked by inconsistencies, exemptions, and overlapping and conflicting jurisdictions. In addition, many non-transportation policies have a serious impact on the transportation sector, but these potential effects are often not considered in advance of adoption. It is also concluded that the Federal government has no accurate calculation of of its expenditures for transportation or of the aid provided by other levels of government to transportation, and that it has limited data on the physical performance of the U.S. transportation system. Appended are lists of the 30 congressional committees and the 64 Federal agencies with transportation responsibility, and detailed descriptions of approximately 1,000 transportation policies and programs.

EXHAUST EMISSIONS FROM VEHICLES IN DEMAND-RESPONSIVE SERVICE

Emission testing was conducted on 11 demand-responsive vehicles (i.e. vans and small buses) used in transportation service designed to attract people away from automobile use and to mass transit for commuting and shopping. Each vehicle was tested using the Federal Test Procedure (FTP) for Light-Duty Vehicles; the Surveillance Driving Sequence, including steady-state modes; and the AA (Ann-Arbor)-1 Urban Bus Cycle, developed by EPA (Environmental Protection Agency). Each vehicle was run at typical inertia loads for all test procedures and fully loaded for the AA-1 cycle. All FTP tests were cold-start; all others were hot-start. Average FTP emissions of hydrocarbons were four times higher than comparable light-duty standards; average carbon monoxide emissions were six times higher, and nitrogen oxides emissions about three times higher. Modal emissions using the composite bag and calculated method agreed well for each of the pollutants. As expected, AA-1 low vs. high inertia weight emissions were less for each pollutant, and fuel economy for the low weight was better. The cold, transient portion of the FTP compared to AA-1 was considerably higher in emissions due to the cold-start effect, but the cold-stabilized portion of the FTP was much closer to the AA-1. (The driving cycle average speeds of both tests are nearly equal and both tests are essentially hot starts.) The data will be used by EPA to estimate emission inventories for demand-responsive vehicles.

MILES' BETTER DRIVING. JOHN MILES' GUIDE TO IMPROVING YOUR TECHNIQUE

John Miles, a Grand Prix driver with Lotus in 1969 and 1970, and now a member of the Autocar test and technical team, offers advice on how to improve one's driving skills. As an
introduction, a guide is provided of items to consider for be
driving. These include regular checkup of the car; cor
driver position to reduce stress, maintain good control,
provide best sensory input; familiarity with the car; concen
tion; smooth driving for maximum fuel economy; careful ro
way positioning; and proper response to highway traffic,
verse weather, broken windows and tire and brake failures.
second section describes and illustrates some potential accid
situations, illustrating the need to be aware of dangers and
know how to take evasive action. Information is given on
vanced driving training, including advanced driving tests adm
istered by the Inst. of Advanced Motorists (IAM) and
League of Safe Drivers (both in London, England), and
vanced driving courses offered by the British School of Mo
ing and by a driving coach, Mike Franey (both located
London). A description is given of the IAM driving test
Tony Howard who has taken the exam. Information is given
skid control schools; a list of skid pan facilities in Englan
provided. Final sections discuss racing driver's schools, incl
ing the disadvantages and advantages of several British scho
and describe the race car driver's technique, to provide ins
for the racing spectator and useful lessons for the every
motorist.

DRIVING FOR ECONOMY. STUART BLADON'S GUIDE TO MONEY-SAVING MOTORING

Stuart Bladon, an acknowledged expert on economy driv
and a reporter on fuel-saving techniques and events, provid
guide to money-saving driving. Based on his many years
competition in fuel economy contests, Mr. Bladon offers adv
on anticipation and concentration in driving, throttle con
and use of gears, freewheeling, coping with a cold engine,
avoiding unnecessary loss of fuel. A checklist is provided
maintenance practices for better fuel economy which covers
ignition, carburetion, fuel system, wheels and tires, brakes,
general items. A fuel-saving device, British patent applica
no. 7919370 by Ian Harris, is described which prevents
being drawn into the engine when the driver's foot is off
accelerator. Autocar test results show a fuel savings of 4%-
with the device. The merits of overdrive for better fuel ec
my are discussed by Michael Scarlett. The sponsorship by
ious oil companies and organization of fuel economy runs by
Hants. and Berks. Motor Club (England) are discussed. A
car's Road Test figures on passenger car fuel economy
presented as a safe basis for comparison of the fuel economy
average motorist might expect from his car. The British "
system for grading (octane rating) fuel at the pump is discu
A final section, by Jeffrey Daniels, examines the diesel car

TRANSPORTATION SAFETY INDEX APPLICABLE TO ALL MODES

The basic classes of transportation safety indices based on time, event, activity, and population have special utility for certain modes, but they lack a common basis and general applicability. A failure index (FI) is presented that can be applied to all modes and can allow cross-modal and intramodal comparisons between air carrier and general aviation, highway, rail, rail rapid transit, vessel, and recreational boats. One of the central concepts in the development of the FI is the identification of the functional differences during a trip throughout its various environments where an environment is defined and classified as a function of a specific segment of a trip. By using available data, the FI is calibrated for the case of passenger fatalities. Among the results are that air was found to be less safe than intercity bus or rail for trips of less than 2400 km (1500 mi) and that, for short trips, air is generally less safe than the automobile. The FI is also used to show how two operators that have the same basic safety performance can appear to differ because of route composition (i.e. trip-length distribution).

CHANGING BASELINE IN TRANSPORTATION SAFETY: AN ASSESSMENT OF SOME KEY FACTORS

Although many countermeasures are introduced to enhance transportation safety, accident experience can vary systematically over time even if no countermeasures are introduced. An examination is presented of factors that cause the safety reference level or baseline to change without other modification of the system. Four case studies are discussed, representative of existing effects on traffic safety: the changing age distribution of the automobile-driving population, the changing urban-rural balance, changes in modal trip lengths or vehicle types, and modal shifts induced by transportation system management actions. Each of these is found to have a significant effect (5% to 10% on the baseline). This analysis illustrates that it is not valid to explicitly or implicitly assume that major societal forces or trends will not cause the safety baseline to change. Key forces exist that will cause future changes in the accident experience large enough to rival or exceed the effects of most rather successful accident countermeasures and that will make some fairly meaningless measures seem useful.

APPLICABILITY OF BEHAVIOR THEORY TO TRANSPORTATION

The applicability of two theories of behavior, humanistic and behavioristic, to two areas of transportation (safety and modal choice) was investigated in two experiments. The underlying hypothesis of a direct relationship between noncompliance with the speed limit and speed control strategy was first tested. One strategy was based on the humanistic theory that variables controlling operating speeds are: depth of penetration of information relevant to speed control consequences; operator's motivation to become self-actualized by seeking a measure of self-control; and success of the reeducative strategy of driver education. A second strategy was based on the behavioristic theory which hypothesizes that the variables controlling operating speed are the past histories of reinforcement and pushishment relative to the operator speeding behavior. Experiment supported the behavioristic theory, finding public information campaigns ineffective. A second experiment tested the premise that the reinforced choices would be made more often in an environment where positive controls reinforce consumer choice of the public transit and carpool options and do not reinforce the private automobile choice. Participants overwhelmingly indicated private car preference when asked to choose commuting mode. Those randomly assigned to reinforcement and combined (reinforcement and incentive) conditions changed their opinion. Incentives (positive year-end consequences) alone were ineffective in controlling driver behavior. These results also support the behavioristic theory.

IMPROVING TRAFFIC SAFETY IN RURAL KANSAS

In southwestern Kansas, where the population density is less than 4 persons/sq km (10 persons/sq mi), there were no local traffic engineering personnel in the 41,150 sq km (16,000 sq mi) area before 1977. The Greater Southwest Regional Planning Commission created a position of regional traffic engineer (RTE) in late 1976 in an effort to improve traffic safety in this rural area. During the first two years, the engineer has involved 29 of the 45 cities in Federally-funded traffic sign improvement projects, completed or initiated analysis at several high-hazard locations, assisted local units of government to become aware of and obtain state and Federal funds, and worked with local government personnel in 18 of the 19 counties to establish some local expertise in traffic safety. The primary benefit of the RTE has been to personalize traffic engineering in southwestern Kansas, where the local units of government could not individually afford and would not need a full-time traffic engineer. Under the commission assistance plan, the engineer is on call to all the local units, and is governed and used by them.

METHODS FOR IMPROVING ANALYSIS OF ROADSIDE SAFETY

The state of the art in roadside safety improvements is reviewed, with particular attention to the roadside-hazard model developed by Glennon (1974). The model depends on the concept that an injury-producing roadside impact is a result of a sequence of four conditional events: the impacting vehicle must be within the discrete increment of roadway associated with a potential collision with the roadside obstacle, a roadside encroachment must occur, vehicle lateral displacement must be great enough for collision with the roadside obstacle, and the collision must be of sufficient magnitude to produce an injury. This sequence of events suggests a conceptual approach for evaluating the degree of roadside hazard. The need is demonstrated for additional research to validate or add precision to the Glennon model. An empirical accident study is suggested that relates the hazard of specific roadside obstacles to design, operating, and environmental variables. The proposed analysis method assumes a Poisson probability distribution and uses Bayes' theorem for the construction of a discrete model for precisely predicting the hazard of any roadside location.

PROCEDURE FOR THE EVALUATION OF COMPLETED HIGHWAY-SAFETY PROJECTS

Based on a revew of the literature and current practices, it was concluded that existing techniques for evaluating effectiveness of highway safety projects are appropriate, but that they should be organized into a structured procedure to provide a step-by-step guide for engineers and highway safety personnel. A procedure is described for performing effectiveness evaluations of completed highway safety projects which is drawn from state-of-the-art techniques. The evolution of the procedure included the development of a guide and a three-day training session and workshop for practicing highway safety engineers. Worksheets and data forms were developed to aid the evaluator. The evaluation procedure consists of six functions, each formulated into a series of systematic steps that guide an evaluator through the activities and decision-making processes of a properly designed study. These functions are to develop an evaluation plan; to collect and reduce data; to compare measures of effectiveness; to perform tests of significance; to perform economic analysis;
and to prepare evaluation documentation. Of five case stu
prepared to illustrate the use of the evaluation methodolo
one abbreviated case study is discussed based on a skid-re
ance treatment to a section of an Interstate freeway.

USE OF TRAFFIC-CONFLICTS TECHNIQUE TO ASSESS HAZARDS OF TRANSPORTING OVERSI LOADS

The traffic-conflicts technique was used to assess the haz
associated with transporting oversize loads over highways.
approach was based on the assumption that a driver ap
brakes in response to a perceived danger when following, p
ing, or meeting other vehicles. Field tests were conducte
determine whether there are any differences in the haz
involved in moving 3.7-m (12-ft) wide housing units as c
pared with those of moving 4.3-m (14-ft) wide units. Altho
an analysis of the conflicts indicated that there were no m
differences, the sample size was too small for the results t
accepted with a high degree of confidence. The conflicts
indicated that the large sample sizes needed to establish sta
cally reliable results may not be practical, but the technique
useful in determining the types and relative frequencies of
ards associated with the movement of wide loads over a va
of highway systems. As a measure for assessing the hazard
moving wide loads, the conflicts technique provided more
tailed information in a short period of time than could
been obtained from a conventional accident analysis.

HIGHWAY ACCIDENT REPORT. FORD COURIE PICKUP TRUCK, FIXED-OBJECT COLLISION, PATUXENT ROAD NEAR CROFTON, MARYLAN APRIL 23, 1979

A compact pickup truck with 12 teenagers as occupants, tr
ing between 64 and 78 mph along a winding country road
Crofton, Maryland, failed to negotiate a curve to the left.
truck ran off the right side of the road and struck three
located about 7 ft from the edge of the pavement. Ten pa
gers were killed, and one was seriously injured; the driver
injured slightly. It was determined that the probable caus
the accident was high-speed, reckless driving by a person
was under the influence of alcohol and marijuana. Contribu
to the severe consequences was the presence of passenge
the open bed of the pickup, an area that offered no c
protection. Ball bank indicator tests showed about 30 mph
an appropriate, comfortable speed for negotiating the c
where the accident occurred. Although the truck's shoulde

belts appeared to have been purposely lodged behind the seat cushions, it was determined that even with lap and shoulder belts properly fastened, the passengers would probably not have survived. The driver probably survived the collision because he was laterally farther away from direct contact with the trees, he was not ejected from the cab, and other passengers cushioned him from the interior of the vehicle. A recommendation is made to the National Com. on Uniform Traffic Laws and Ordinances to establish model guidelines for prohibiting passengers from riding in open-cargo areas of vehicles being used for nonwork-related purposes.

EXPLAINING SAFETY HELMET USE BY MOTORCYCLE OPERATORS USING A BEHAVIORAL INTENTION MODEL

The major purpose of this study was to investigate helmet-use behavior of motorcycle operators using the Fishbein Model for the prediction of behavioral intentions. Data were collected during personal interviews at motorcycle dealerships on a multistage cluster sample of 235 motorcycle operators in Illinois, a state without a helmet use law. A follow-up telephone survey of the sample was conducted to obtain self-reported data on subsequent helmet use behavior (50% response rate). Results show that 53% of the variance in behavioral intentions to wear a helmet when riding a motorcycle could be explained from attitudinal and social-normative factors. The decision to use a helmet was found to be primarily under attitudinal rather than social-normative control. Subjects who intended to wear a helmet generally had stronger beliefs about safety, minimized discomfort and inconvenience, and were less likely to hold inaccurate beliefs about alleged helmet disadvantages than nonintenders. There was no discrimination for social image, and no evidence that perceived susceptibility or seriousness influenced beliefs. Self-reported frequency of helmet use was associated with certain variables: motorcycle make, engine size, participation in motorcycle safety course, education level, membership in organized motorcycle club and American Motorcyclist Assoc., and self-reported frequency of seat belt use, and several motorcycle operating conditions. Findins indicate that nonintenders are generally not as informed about safety consequences of helmet use as are intenders. A social policy stressing an informational as well as legislative approach to the nonuse problem is recommended.

NEW YORK STATE ALCOHOL AND DRUG REHABILITATION PROGRAM. INTERIM EVALUATION

Drivers exposed to the New York State Drinking Driver Rehabilitation Prog. (DDRP) were found to have a lower conviction rate for alcohol-related (A/R) violations for a post-treatment period (Apr-May 1976 thru Sep-Oct 1977) than for a pre-treatment period (Sep-Oct 1974 thru May-Apr 1976). This finding is consistent with an Oct 1978 Status Report on the DDRP (appended). DDRP drivers had a lower conviction rate for all types of traffic violations following treatment when compared with a sample of all drivers with at least one conviction. DDRP drivers experienced a significant reduction in both number and rate of accidents. Drivers who completed rehabilitation programs, including drivers not granted a conditional license privilege, exhibited significant reductions in the incidence of all convictions, A/R convictions, and accidents following treatment. Drivers who did not complete the program, but who had some classroom instruction, exhibited fewer post-treatment A/R violations and fewer accidents than in the pre-treatment period.

PASSENGER COMFORT--AN OVERVIEW

The concept of comfort (riding, local, and organizational) and its relationship to travel experiences of passengers is considered. Papers in this special issue are intended to emphasize and elucidate aspects of Mayr's (1959) riding comfort analysis (subjective, technical/structural, psychological, and physiological factors). Factors in the transport environment likely to influence comfort are reviewed, with pertinent studies cited. These secondary, marginal, and integration factors, as opposed to primary comfort factors considered in the basic vehicle design stage, include temperature, ventilation, illumination, photic stimulation (giving rise to "flicker vertigo"), train or photokinetic nystagmus, pressure change on the ear, journey length, and task impairment (e.g. reading or writing) by vibration and noise.

VIBRATION AND PASSENGER COMFORT: CAN DATA FROM SUBJECTS BE USED TO PREDICT PASSENGER COMFORT?

Field and laboratory studies of human reaction to whole-body vibration are reviewed in an attempt to determine to what extent laboratory results may be used to predict comfort levels for passenger vehicles. The aim of some studies has been to describe the manner in which human response to vibration varies over a specific frequency range, by ascribing descriptive comfort labels to contours of equal subjective intensity. Studies including both laboratory and field situations used subjects other than fare-paying passengers. These studies show that little agreement exists among various investigators on the difference between "comfortable" and "uncomfortable" levels of vibration. More recent studies, all inconclusive, investigate human reaction to vibration simply in terms of equal sensation curves without reference to any one particular comfort level. Some attempts have been made to combine existing information to provide criteria or standards for determining human reaction to vibration. From this review, it is concluded that laboratory data may be used by the design engineer, provided their limitations are realized. Although the data will not precisely predict passenger reaction, any discrepancy will cause the engineer to tend to err on the side of reducing vibration levels below those required by the passenger.

MODELS OF HUMAN REACTION TO VEHICLE ENVIRONMENTS

Extensive field studies have been conducted to determine the physical correlates of perceived comfort for passengers in vehicle environments. Passengers' experiences of comfort were assessed upon exposure to various levels of motion, noise, temperature, pressure, and different seats and spatial arrangements. For each of the many vehicle types studied, models were developed relating physical variation to rated comfort. Some similarities in these models suggest that a composite model for human reaction to all vehicles may be feasible. The mathematical formulations are simple multiple regression equations. Air mode studies have shown that comfort is a function of vertical and transverse accelerations, noise levels, and seat factors, as well as maneuver conditions. Comfort models for ground-based vehicles (buses, trains) involve roll rates and noise levels.

FURTHER COMPARISONS OF COMPUTED AND MEASURED DIVIDED-CHAMBER ENGINE COMBUSTION

Combustion in a divided-chamber, stratified-charge engine is considered, and flame and pressure results obtained with a two-dimensional unsteady model are compared with corresponding engine data. The model is applied to eight engine conditions differing in speed, load and size of the prechamber orifice. The model employs one overall chemical reaction rate, the turbulence energy and its dissipation rate, and a wall heat loss proportional to the heat release. The computed results are shown to be in good agreement with the experimental ones in spite of the complexity of the problem and the early stages of detailed model validation studies. They are also shown to compare somewhat better than earlier ones obtained with an ad-hoc jet turbulence model. Both studies prove the importance of the prechamber jet to the overall combustion process for the particular engine investigated. Since divided chamber configurations are considerably more complex than open chamber ones, the model should be applicable to a variety of engine designs. Current and past experience indicates the model should be particularly useful in combustion optimization studies, during engine development, as a means to interpret and extrapolate engine test data.

THE EFFECTIVENESS OF AUSTRALIAN DESIGN RULE 22 FOR HEAD RESTRAINTS

Australian Design Rules (ADR) 22 and 22A are described which require head restraints on driver and front left seats of all new cars in Australia, beginning with 1972 models. The effective heights of these restraints are discussed, as well as the nature of whiplash injuries which they are designed to prevent. Studies of head restraint effectiveness are reviewed. Data on 1974-1975 claims to the Motor Accidents Board in Victoria for injury compensation are analyzed to evaluate the effectiveness of ADR 22. Potential benefit groups (front outboard seat occupants in rear-end impacts) and disbenefit groups (rear seat occupants in front-end impacts) are considered, as well as other occupants and crash circumstances as a control for crash severity differences. It is concluded that there is weak evidence that ADR 22 is effective in reducing whiplash injuries sustained in rear impacts. The benefit is almost entirely confined to female occupants of front left seats. There is no evidence of disbenefits in terms of head or facial injuries to rear seat occupants. There is evidence of disbenefits in terms of whiplash and major intracranial injuries to drivers involved in frontal impacts in ADR 22 cars compared with pre-ADR 22 cars. The absence of information on crash severity and seat belt use precludes definitive conclusions.

THE EFFECT OF SEAT BELTS ON MINOR AND SEVERE INJURIES MEASURED ON THE ABBREVIATED INJURY SCALE

Following the implementation of compulsory seat belt use legislation in Victoria, Australia (Dec 1970), the Royal Australasian Coll. of Surgeons established a survey to collect detailed injury and crash data on car accidents in that state. An analysis is reviewed of the effect of seat belt use on severe injuries sustained by car occupants during the first two years of the survey as reported by Cameron and Nelson (1977). Also reviewed is an extended file covering 8537 occupants injured during the first three years of the survey with the injuries (including minor ones) coded according to the Abbreviated Injury Scale. The effect of seat belt use on both minor and severe injuries is examined, with some comparisons between injury severity distributions in the Victorian data and those from data collected in the U.S. by multidisciplinary accident investigation teams. It is concluded that the wearing of static three-point lap/sash belts by front outboard occupants is associated with reduced likelihood of severe-to-fatal injuries to the head-face, thorax, lower torso, and lower extremities for crashes in urban areas and for occupants injured but not ejected, and to some body regions for rural crashes. It is also concluded that for these same occupants, seat belt use is associated with increased likelihood of minor injuries to the thorax and lower torso in both rural and urban accidents, and increased likelihood of minor neck injury (i.e. whiplash) in urban accidents. The absence of crash severity data precludes a definitive evaluation of seat belt effect alone on injuries.

HS-027 275

EFFECT OF DRIVER'S AGE ON NIGHTTIME LEGIBILITY OF HIGHWAY SIGNS

A field investigation was performed of the effect of driver's age on nighttime legibility of highway signs, using subjects in two age groups (under 25 and over 61 years of age), screened by tests for color vision and far acuity under high and low luminance (80.5-2.3 cd/sq m). The results confirm those of previous laboratory tests, demonstrating that the legibility distances for older subjects were 65% to 77% of those for younger subjects with equal high-luminance visual acuity. An important implication is that older drivers are likely to have less time available in which to act on sign information. Consequently, it is argued that legibility standards for highway signs should not be based exclusively on data obtained from young observers, and that standard (high-luminance) acuity tests have questionable relevance to nighttime visual performance.

ELECTRIC CARS FOR URBAN TRANSPORTATION

An investigation of the effects of large-scale use of electric cars on energy, the environment, and the economy in the U.S. is summarized. If all automobiles in the U.S. were electrified by the year 2000, petroleum requirements for automotive travel would be reduced by 83%. Electric cars would substantially reduce the regional emissions of pollutants primarily due to vehicles (hydrocarbons and carbon monoxide), although this would be offset by increases of up to 20% in sulfur oxides emissions due to fossil-fueled power plants that generate recharge power. Substitution of electric cars for all internal combustion cars would reduce noise impacts by almost half, to about 20% of the 1974 level. Despite their availability from a major manufacturer by 1990, sales of electric cars are expected to be relatively modest (under 10% of the U.S. automobile fleet in the year 2000). Although future electric cars will be capable and economical, they will still cost somewhat more and do somewhat less than competing conventional automobiles. Where pollution, conservation, and continued high mobility are important considerations in transportation system planning, electric cars deserve to be considered along with such frequently proposed measures as parking restrictions, exclusive bus and carpool lanes, automobile taxation, and transit subsidy.

HS-027 278

ASSESSMENT OF MARKET POTENTIALS FOR ELECTRIC VEHICLES

The development and application of a market assessment model is described which analyzes the potential for the substitution of electric vehicles (EV's) for conventional vehicles by identifying generic vehicle type and user groups, and determining the compatibility of an EV to the travel and service requirements of the user groups. The model uses stratified household travel data to simulate typical daily travel patterns throughout the year. Alternative scenarios of vehicle use are introduced to relate the sensitivity of the market potentials to household travel behavior. An approach to analyzing commercial EV market potentials is also presented. Results of passenger vehicle analysis reveal the interrelationships among the vehicle range distributions, the patterns of vehicle use, and the household travel characteristics, specifically trip frequency and length. Changes in use patterns or travel behavior can have a pronounced impact, both positive and negative, on EV range requirements. Changes may also be brought about by technology or market factors as well as by changes in lifestyle, which are quite independent of transportation system factors. It is suggested that the introduction of low- to medium-range EV's will have only a marginal effect on reducing petroleum consumption. Much more information is needed before credible sales estimates can be made. In the interim, systematic market potential estimates can play an important role in EV technology and resource allocation decisions.

DEVELOPMENTS IN AUTOMOTIVE ELECTRONICS

The current state of the art of automotive electric systems is reviewed, with particular emphasis on systems which improve driver safety and vehicle efficiency. A discussion of cost and reliability concludes that from 1980-1981 onward, the cost of electronic-components will no longer be a major inhibiting factor, and that between 1979 and 1981, the reliability of electronic components/systems will improve to a point where they will offer a substantial benefit over mechanical or electromechanical systems. The main features of six vehicle systems in which electronics will likely be important or dominant elements by 1985 are described. These are: engine management, transmission control, electronic instrumentation, traffic and road information, multiplex ring main distribution, and antiskid brakes. Details are included of how microprocessor or minicomputer techniques are used in these systems. Minor systems in which electronics will have an increased role are mentioned: electronic headlamp dip/dim systems, automatic temperature control, seat belt and other safety system monitoring and warning, speed control, and driver diagnostics for fluid levels, bulb failure, brake pad wear, and tire pressure. Two areas in which significant development is likely are suspension rate and deflection control, and vehicle collision warning radar.

TURBOCHARGING WITH THERMAL REACTOR, EGR (EXHAUST GAS RECIRCULATION) AND ALCOHOL-GASOLINE MIXTURES

Experimental studies on a mildly turbocharged (TC) spark ignition engine with thermal reactor demonstrated that it is feasible to use alcohol to extend the octane rating of gasolines, but indicated the need for correct timing and carburetion for each alcohol-gasoline mixture to obtain optimum economy. Up to 30% alcohol doped fuels behaved in a similar manner to pure gasoline in this TC engine. The alcohol did not appear to affect the carbon monoxide or nitrogen oxides (NOx) emissions, but alcohol concentrations of 20% or more increased hydrocarbon emissions. Of various concentrations of exhaust gas recirculation, the best quantity was found to be approximately 5% by volume, which gave a large reduction in NOx emissions and little loss of fuel economy or performance. The 2-litre TC engine is rated at 69 kW at 4000 rpm WOT (wide open throttle) and, with a peak torque of 170 Nm at 2500 rpm WOT available, an effective torque curve for normal passenger car use is obtained.

FUEL ECONOMY AND EMISSIONS OF LEAN-BURN ENGINES. CONFERENCE REPORT

Various papers delivered at a recent Institute of Mechanical Engineers Automobile Div. conference in London are reviewed,
which cover fuel economy and emissions of lean-burn engi
Two important points to come from the meeting are that
fundamentals of air movement and combustion are finally be
widely investigated, but that production versions of lean-b
engines will not be realized for a long time. These engines o
fuel consumption reductions with low emissions. Although
emission levels are not low enough to meet U.S. and Japan
standards without some additional treatment, they could m
future requirements in Europe. Individual research efforts
scribed cover lean burning in three different engines, mix
devices in the induction system, turbulent-flow manifolds, a
on devices to improve performance and reduce fuel consur
tion, modeling of mixture formation in the intake manifold,
swirl and squish, incompletely burned cycles, and dual ignit
systems. In a summation of the conference, it was ackno
edged that high-compression lean-burn engines offer the pot
tial of a 20% reduction in fuel consumption and therefore m
attention, but that the questions about emission remain un
solved.

WARNING: SOMETHING ISN'T QUITE RIGHT HERE (CLUES TO IMPENDING ROADWAY DANGERS)

Road users are advised to be alert to certain warnings of
proaching danger, in order to reduce accident numbers. A c
scious effort should be made to drive defensively and anticip
dangerous situations before they occur. A defensive motor
for example, recognizes the signs of a drunk driver and is aw
that a rolling ball on the street is likely to be followed b
child. A defensive bicyclist is constantly on the alert fo
parked motorist who might pull out or open a car door into
path. A defensive motorcyclist is alert to oil on street surfa
A defensive pedestrian never gambles on a right-of-way w
crossing in a crosswalk or with a green light. A defensive r
user has to be a part-time psychologist. Many of the less "ol
ous" warning signs of impending danger require some comn
sense and logic. For example, a driver would do well to
ceed with extreme caution if he notices a sudden absence
traffic in the other lane as he approaches a blind curve; this
indicate an accident ahead. Noticing the situation not only a
develops, but before it develops, is the key to staying alive
our nation's roads.

GUIDELINES FOR THE APPLICATION OF ARRO BOARDS IN WORK ZONES. FINAL REPORT

A study to develop objective criteria for the use, design,
placement of arrow boards in roadway work zones is repor
The study included a review of the literature on work z
traffic control; human factors investigations of driver infor
tion requirements, expectancy, and understanding of ar
boards; and an intensive field study of driver responses to ar
boards in actual work zones. Studies were made of 26 constr
tion sites and 23 hours of maintenance activities. Each phas

the study is described; appended are definitions of terms, the arrow board guidelines, detailed field study results, and a description of the statistical approach used to determine significant effects of arrow board use. The research determined that arrow boards were effective in lane closure work zones because they promoted earlier merging into the open lane and fewer vehicles remained in the closed lane at the start of the lane closure taper. The arrow board was more effective when placed on the shoulder of the roadway near the start of the lane closure taper. Arrow boards were not found to be generally effective in traffic diversions or splits or for moving shoulder closures. They did, however, prove effective in reducing some specific operational problems in these types of work zones.

TRAVEL AND THE HANDICAPPED: A PROJECT SUMMARY

The main findings of a series of related studies of the travel characteristics and problems of physically handicapped people are summarized. The studies included a survey of organizations for handicapped people, a travel behavior study of selected handicapped persons, surveys of physically handicapped travelers and nontravelers living in Coventry, England, and a literature survey (TRRL-WP/10). Walking was found to be the most frequently used form of transport for handicapped persons, followed by car, then bus; other modes did not provide a significant amount of mobility. Problems were encountered in using pedestrian facilities as a result of width, uneven surfaces, and changes in level at curbs. Wherever possible, the handicapped individual would benefit from the minimization of walking distances and the provision of seats at strategic points such as bus stops and interchanges. The provision of wide and level access to public transit vehicles, and of alternatives for level changing at terminals, would greatly reduce the number of obstacles facing the handicapped traveler. It is important that changes in level are reduced to a minimum for all modes of transport. Operational rather than design factors presented difficulties for handicapped persons riding buses (e.g. bus moving before passengers seated, stopping too far from curb). Information about special facilities provided by British Rail for elderly and handicapped persons needs more publicity. Some form of door-to-door transport appears to be the only means of meeting any potential travel demand from the more seriously handicapped population.

CYCLE ROUTES IN PORTSMOUTH. 2--TRAFFIC STUDIES (SPECIAL BICYCLE ROAD SYSTEM, ENGLAND)

An experimental bicycle route network operating between Nov 1975 and Jun 1976 in Portsmouth, England, was evaluated in the following terms: effectiveness of special traffic management techniques (the central lane marked as a cycle lane, special junctions intended to bar through motor vehicle traffic, one-way streets for motor vehicles on two route sections, and "all motor vehicles prohibited" signs); changes in motor vehicle and bicycle flows resulting from the introduction of the cycle route; and changes in the number of accidents. The routes, 6.3 km in total length on residential roads, were designed to provide a quick, safe, and convenient roadway system for bicyclists between selected residential areas and certain schools, shopping areas, and workplaces. Motor vehicle traffic was prohibited except for local access at designated points. It was found that substantial proportions of motorists did not obey the various restrictions. The central lane operated as intended and the cyclists did move into the center of the road where they were more conspicuous and the surface was better. There were operational difficulties with the lane, however, as motorists had difficulty passing on the inside of cyclists. Motor vehicle traffic flow was reduced by about two-fifths. Cycle flow rose by about one-third, at least half attributable to the experimental measures. No significant changes in the number of accidents involving bicyclists were detected during the experiment as the annual numbers of accidents before and during the experiment were low.

CYCLE ROUTES IN PORTSMOUTH. 3--ATTITUDE SURVEYS (SPECIAL BICYCLE ROAD SYSTEM, ENGLAND)

An experimental system of bicycle routes was in use between Nov 1975 and Jun 1976 in Portsmouth, England. The routes, 6.3 km in total length, on residential roads, were designed to provide a quick, safe, and convenient roadway system for bicyclists between selected residential areas and certain schools, shopping areas, and workplaces. Motor vehicle traffic was prohibited except for local access. Attitude surveys conducted three and six months after the opening of the routes indicated that most residents on the routes considered that they had been unaffected by the scheme or were actively in favor of it. Most cyclists had a favorable opinion, but greatly criticized motorists for ignoring traffic signs along the routes and for lack of consideration for cyclists. About half of the 39 shopkeepers on the routes claimed that they had lost some business because of the system. Most of the complaints from a sample of motorists concerned the need to make detours. Apart from adequately meeting its design aims, the experiment provided valuable information on the operation and monitoring of cycle routes and on public attitudes. The information was used to plan and monitor more advanced cycle routes in other British cities.

THE EDGE-LOCKING PERFORMANCE OF SOME SEAT BELT INERTIA REELS

Six designs of inertia reel seat belts from two British manufacturers (Britax (Wingard) and Kangol), some current models and others no longer in production but still in use, were tested to identify possible problems relating to the malfunction of the locking mechanism under heavy braking or impact conditions. The malfunction known as "edge-locking" (tip-to-tip tooth engagement of a locking pawl or cog), was specifically investigated. A few samples of certain inertia reels which appear superficially to function correctly, did not lock correctly on a small number of occasions in car impacts. Improvements in the design and construction of some models seem necessary if edge-locking and excessive reel-out in accidents are to be avoided. The best estimate of the rate of faulty operation in severe accidents (50kph) for both the Britax Autolok MkIII and MkIIIA is about 2%. The Britax Surelok, Kangol Reflex, and Kangol Euroflex appear to be superior in this aspect of performance. There was no failure of the Surelok and Euroflex in these tests. If assembled correctly, the Kangol Series 12 reel appears to be satisfactory. Of the 20 reels of this design examined, only one appeared to have a manufacturing fault. The best estimate for the rate of faulty operation of this reel is 1% in severe accidents. There is a case for an appropriate test in the relevant standards and regulations to assess the risk of reel-out following edge-locking.

CAR BUYING FOR THE '80S

Some insight is given concerning what the prospective car buyer can expect on the market in the 1980's: smaller size, turbocharging, front-wheel drive, more microprocessor applications, run-flat tires, air bags, and possibly, antiskid brakes. However, it is stated that, essentially, what is available today is what one will be able to get in 1985. The potential for various alternative powerplants is assessed, including electric systems, the Stirling cycle (external combustion), the Brayton cycle (gas turbine), and fuel cells. The consumer, whatever his particular view of the future, is advised to contemplate the kind of economic, political, and social changes there might be and make some judgments about how they will affect his car ownership. Some new or imminent marketing techniques confronting the car buyer are reported in a separate section: the price pack or return to the dealer practice of adding extra charges to the price sticker (e.g. "delivery and handling" charges, "profit"), long-term installment contracts, extended warranties, leasing, and more wariness on the part of dealers in making unfounded claims in light of increasing consumer protection. Another section advises the prospective buyer to determine actual automotive needs, make money choices, buy no more car than is needed, and inspect the car before taking delivery.

HIGH-GRADE FUELS FROM BIOMASS FARMING: POTENTIALS AND CONSTRAINTS

The key parameters controlling the productivity and the cost of net high-grade fuel from a system for biomass agriculture and conversion are analyzed. Performance depends on a "symbiotic" interaction between agronomy and conversion technology. This includes, in agronomy, high-grade fuel energy support of agriculture, and in technology, energy efficient conversion. The conditions for obtaining net productivity and costs are explored, with U.S. grain alcohol as a reference point. Currently practical technology consumes more high-grade fuel (petroleum and gas) than it generates in the form of grain alcohol. Some potentials and constraints for future systems are explored, including use of other plant species and conversion systems. Positive net productivity can be attained, but it requires the elimination of high-grade fuel input to the alcohol process facility.

A FIFTEEN-COUNTRY STUDY OF SOME FACTORS INFLUENCING THE NUMBER AND THE SEVERITY OF ROAD ACCIDENTS. PT. 1. BACKGROUND FACTS AND STATISTICS (UNE ETUDE DANS QUINZE PAYS DE QUELQUES FACTEURS DETERMINANT LE NOMBRE ET LA GRAVITE DES ACCIDENTS DE LA ROUTE. PARTIE 1. DONNEES ET STATISTIQUES DE BASE

An overview is provided of road accidents as a major economic, social, and public health problem. The creation of the International Drivers' Behavior Res. Assoc. (IDBRA) in 1970, and the organization's research objectives and initial achievements are described, including completion of first cross-national driver behavior research project and organization of the First International Conference on Driver Behavior. Conflicting goals among special-interest groups are mentioned as deterrents to road safety progress. Some immediate and long-term effects of the energy crisis on road safety are discussed. Difficulties encountered by IDBRA in its cross-national analyses of road transport and accident information and statistics are described, as are tabulated data derived from the analyses and current approaches being taken by IDBRA to improving road accident statistics. The need to study the various factors that influence the number of road accidents and their severity, with particular emphasis on human factors, is addressed. Comparative statistical tables from IDBRA's cross-national study are included for 14 of the 15 countries studied (U.S.S.R. excluded): Belgium, Switzerland, Federal Republic of Germany, Denmark, Spain, France, U.K., Israel, Japan, The Netherlands, New Zealand, Sweden, Yugoslavia, and South Africa.

A FIFTEEN-COUNTRY STUDY OF SOME FACTORS INFLUENCING THE NUMBER AND THE SEVERITY OF ROAD ACCIDENTS. PT. 2. DRIVERS' ATTITUDES AND OPINIONS (UNE ETUDE DANS QUINZE PAYS DE QUELQUES FACTEURS DETERMINANT LE NOMBRE ET LA GRAVITE DES ACCIDENTS DE LA ROUTE. PARTIE 2. LES ATTITUDES ET LES OPINIONS DES CONDUCTEURS)

Results are presented of a comparative survey of the following nine countries concerning drivers' attitudes and opinions on various aspects of road safety: South Africa, Spain, France, U.K., Japan, Federal Republic of Germany, Sweden, Yugoslavia, and U.S.S.R. Characteristics of the sampled driver populations are also provided (age, sex, vehicle usually driven, socio-economic category, community size, and accident history). It was found that there is apparently a great similarity in the opinions expressed at the cross-national level. The rank order of responses to multiple choice questions is practically identical in all of the surveyed countries. The Japanese results show the least conformity with the overall findings. The Soviet Union, Sweden, and the U.K. had the most moderate replies. The spread in the degree of agreement among countries varies considerably according to the particular question. Replies with a wide spread concerned the following items: frequency of seat belt wearing, risk-taking when being followed by another vehicle, agreement that overtaking is the most dangerous maneuver, belief that human factors are the most important cause of accidents, belief that changes in the layout of roads is the priority improvement for road networks, and belief that one drives more safely than other drivers. Replies with a narrow spread involve the following items: belief that other drivers do not keep to speed limits, belief in the increased risk of being injured in a road accident during the next ten years, opinion that inattention is the principal human cause of accidents, importance of the role of alcohol in accidents, recognition of driver training and testing as a priority need, and agreement that headways are insufficient on high-speed, busy roads.

SIMULATION TECHNOLOGY AND TRAFFIC ACCIDENT RECORDS SYSTEMS

Eight papers are compiled which individually discuss simulation technology as applied in transportation areas or traffic accident records systems. The following topics are covered: maritime research at the Computer-Aided Operations Res. Facility (National Maritime Res. Center, Kings Point, N.Y.); the Santa Fe Railway's locomotive engineer training program (which utilizes a locomotive and train simulator); automobile research simulators; computerized street index for the Michigan accident location index system; automated collision (roadway) diagrams; development and use of a data base of commercial vehicle accident in California; and analysis of bicycle delays at intersections and crossings by computer simulation.

AUTOMOBILE RESEARCH SIMULATORS: A REVIEW AND NEW APPROACHES

The capabilities of the following kinds of research-oriented driving simulators (listed by type of visual display) are reviewed: electronically generated imagery, digital computer-generated imagery, point light source, movie film, and scale models (terrain board or endless belt). The basic elements of a general, fixed-base driving simulator are described. Two approaches to driving simulation are discussed in detail as examples of the state of the art of visual display. The first represents a hybrid approach, in which analog and digital computers and electronic circuits are combined to accomplish the various computational requirements. The second approach, which is primarily mechanized, uses a digital computer in which simulator control is accomplished mainly by means of high-level language software. The advantages that simulators have over other approaches are salient factors, safety, cost, experimental control, and performance measurement. Anticipated future developments in simulation technology related to research, driver training, and licensing applications are discussed. Simulator operational factors to be considered in cost-benefit considerations are outlined, including requirements for visual display, motion, audition, and controls.

DEVELOPMENT OF A TRAFFIC RECORDS SYSTEM FOR LOCAL JURISDICTIONS

A traffic records system for small and medium-sized cities and counties has been designed for maximum utlization of manual record-keeping procedures and for use as a supplement to existing criminal justice records. The system was developed on the basis of a survey of existing traffic records systems in Tennessee and a review of the literature on traffic records system development. The three basic components of the system are input data, a filing system, and output reports. Each component consists of mandatory and recommended elements. Basic input data may include accident report forms, supplemental accident-related reports, citation records, alcohol influence reports, complaint reports, and enforcement records. The elements of the filing system may consist of accident report files, spot map, driver record file, location file, complaint file, enforcement file, and alcohol influence report. Output reports may include the accident summary, high-accident-rate location summary, spot map, selective enforcement summary, alcohol influence summary, and special reports. Three levels of record keeping are recommended, depending on the volume of traffic records and the capabilities of each jurisdiction. A manual was developed for use by cities and counties in organizing and maintaining a records system and for use as a text for traffic records seminars. A follow-up project is planned in which a series of seminars on the use of the system will be conducted throughout Tenessee.

COMPUTERIZED STREET INDEX FOR MICHIGAN ACCIDENT LOCATION INDEX SYSTEM

The Michigan Dept. of State Police and Dept. of State Highways and Transportation have developed a comprehensive, computerized system of accident inventory called the Michigan Accident Location Index (MALI). The 192,000 km (120,000 mi) of the state's roadway network were computerized in three tasks: data coding, data entry, and resolution of edit and cross-reference errors. The use of computer programs resulted in fast, accurate, and cost-effective methodology. The MALI system is designed to generate a computerized description of traffic accident locations directly from the physical location information observed and reported by police officers. Through this system, identification, surveillance, and maintenance of hazardous locations will be facilitated. All accidents are referenced by distance and direction from the nearest cross-street intersection. The MALI system is designed to produce a variety of accident reports on a county-by-county basis. Currently, 34 counties are fully indexed and on-line: the remaining 49 counties are in various stages of being merged with the master accident file.

AUTOMATED COLLISION DIAGRAMS

Software to produce automated collision diagrams was developed to satisfy a need of the Traffic Improvement Assoc. of Oakland County, Mich. This nonprofit organization, supported by public and private donations, supplies traffic engineering services to more than 30 political jurisdictions in that county and maintains a comprehensive accident inventory. The software, designated the automated collision diagram system (ACDS), is user oriented and requires only minimal familiarity with computer operations. The system uses existing computer-based accident files directly, is cost-effective to use, and produces a realistic representation of accident experience at a specific location, either an intersection or a roadway segment. The collision diagram produced by ACDS, by virtue of its represen-
tation of each accident by a single symbol and its color
of accident severity, produces better results and provide
insight into accident experience at a location than do
systems that produce only one symbol for each type of ac

COMMERCIAL VEHICLE ACCIDENT FACTOR

A 12-month study of commercial vehicle accidents in Ca
was conducted to establish and evaluate appropriate da
development procedures and statistical analysis techniqu
to derive inferences about accident causation and the p
for possible countermeasures. As an extension of an earlie
covering 925 collision reports this study involved 2097 a
al reports from the same study areas of Sacramento, a
Angeles. The characteristics of the sample and the form
procedures used in data collection and reduction are
rized. Selected results of univariate analyses are summ
under four categories: accident factors, involved com
vehicle factors, non-commercial vehicle factors, and hum
tors. A selected set of cross tabulations exhibiting joint f
cies of certain combinations of variables are reported. A
is described which explains or predicts the occurrence o
cle jackknifing as an accident cause by incorporating all
individual two-way interactions between jackknifing bef
cident and road surface, lockup, and number of drive
Results of contingency table analyses are presented, relat
occupant injury severity to road type, truck type, and
weight; brake-related accident to vehicle category an
direction; and commercial vehicle accident to vehicle con
tion, weight, and exposure. Vehicle exposure was found
important in explaining accident occurrence, though not
portant as configuration and weight. Areas for future st
recommended.

ANALYSIS OF BICYCLE DELAYS AT INTERSECTIONS AND CROSSINGS BY COMP SIMULATION

Computer simulation models were developed to anal
delay to bicycles and motor vehicles at crossings and i
tions where the two types of vehicles interact. The o
was to generate some understanding of the level of d

each type of vehicle under various methods of traffic control and combinations of traffic conditions. Observational experiments on bicycle traffic behavior and interactions between bicycles and motor vehicles were carried out in the field, and the models were structured based on these data. The simulation models gave a fairly good representation of delays at intersections and crossings under various methods of traffic control, but the models cannot establish appropriate criteria and warrants for selecting traffic controls. Values and other subjective bases play an essential role in determining the trade-offs between delays for bicycles and for motor vehicles, and between safety and efficiency. The simulation data can provide a quantative basis for exploring standards.

STATE RESOURCES FOR FINANCING TRANSPORTATION PROGRAMS

Severe problems faced by the states in financing their transportation programs in the 1970's are examined, including a review of current methods of financing and potential sources of revenue. The highway user tax system, individual highway user charges, and state tax systems are discussed, as well as findings and suggestions. Statistical data are appended to illustrate trends and variations in financing practices among the states. Reasons for the state transportation financing crisis include: a revenue base not responsive to inflation, a relative slowdown in motor fuel consumption (principal source of revenue), soaring costs, greater sensitivity to social and political pressures, and increasing demands for transportation facilities and services. Motor vehicle fuel efficiency improvements and conversion to new energy sources will worsen the situation. The dedication of highway funds has tended to isolate highway financing from the mainstream of policy making. The highway user charge system has fallen prey to inflation. There is no hidden revenue fountain to rescue the states, but appropriate revenue levels can be achieved by current financing methods. A diverse state and local tax structure tends to minimize tax competition among jurisdictions. Revenue issues pertain mainly to the distribution of the burden. A judicious combination of general tax subsidy and total benefit financing might promote equity and minimize excess burden. An institutional framework that will facilitate adjustments in the revenue structure appears necessary.

DESIGN OF A FAST START GLOW PLUG CONTROL SYSTEM FOR DIESEL ENGINES

The design of a rapid warm-up glow plug thermal control system for General Motors' diesel cars is described. The new system attains glow plug operating temperature in about 6.5 sec, compared to 60 sec for its predecessor. The system design is based on feedback control of a thermal model of the glow plugs. As used in 1979 GM vehicles, the system not only provides an order of magnitude reduction in preglow time, but actually decreases the total energy input required from the battery. The system comprehends vehicle voltage, rendering the glow plugs immune to temperature variations as a function of voltage. These features should give the diesel engine wider public acceptance by reducing the difference in starting practice between spark ignition and diesel engines. Appended is the derivation of the modeling equation.

USE OF A COUETTE HIGH-SHEAR-RATE VISCOMETER FOR MEASURING THE VISCOSITY OF ENGINE LUBRICANTS

The Couette viscometer is described for measuring the viscosity of engine lubricants. A novel feature of the instrument is an electrical capacitance method for determining the size of the annular gap. The heat generation rate in the viscometer can be minimized by making the annular gap small. The device allows one to avoid the use of high pressure and to apply a uniform shear rate. The main technical difficulty involves uncertainties about dimensions of the annular gap. The gap may be uneven due to problems in machining cylinders to fine tolerances; it may fluctuate during measurements because of inner cylinder wobbling and/or eccentric motions; it may increase due to service wear; and it may be affected by sample injection pressure and temperature changes. Operating procedures (steady and stop-start running) are detailed, and mathematical corrections are established for dealing with temperature rise in the test sample. Viscometric data are presented for both single-grade and multigrade oils.

ROADWAY-DRIVER COMPATIBILITY

The motor vehicle transport system is examined in relation to safety and human behavior. Historically, only two events reversed the yearly traffic casualty rate. The first was gasoline rationing and a 45-mph speed limit during World War II. The secnd was the 55-mph speed limit to conserve energy. Traffic control on streets and highways must recognize the safe stopping sight distance (SSSD) concept defined by the American Assoc. of State Hwy. Officials. Problems in providing a SSSD pertain to the time needed by drivers for perception and reaction, condition of road surface where an emergency stop occurs, erroneous assumption that heavy trucks and automobiles can operate with the same SSSD, and assumption by highway authorities that all brake and tire systems respond instantaneously to driver input. Roads and streets can be improved by universal adoption of the SSSD as a standard. Intersections can be carefully designed and controlled to minimize accidents. Understanding driver capability is vital at these locations. Even intersections with a 90-degree configuration create impossible visual conditions for many drivers. Railroad grade crossings are specialized intersections where trains and motor vehicles conflict. Apparent restrictions in roadway width require driver recognition and improved traffic control. No-passing zones are intended to aid the driver when evaluating safe passing sight distances relative to road configuration. The 55-mph speed limit has reduced traffic casualties by adjusting vehicle speed to a rate compatible with human control, but a primary fault of the motor vehicle transport system is the lack of time allotted for drivers and vehicles to respond appropriately to an emergency situation or normal traffic control directives.

ASSESSMET OF SHEAR STABILITY METHODS FOR EUROPEAN ENGINE OILS

High-temperature permanent and temporary viscosities of oils run in a diesel injector shear stability test (DISST) were compared with similar data for two European laboratory engine tests (Peugeot 204 Shear Stability Test; Cortina High Temperature Test), and tests on a High Shear Rate Capillary Viscometer developed by Texaco. A field test was also conducted. Four multigrade oils were used that differed in the polymer thickener and the ratio of base oils used. Measurements of engine oil viscosity at high shear rates and high temperatures provided a more useful characterization than standard viscosity measurements at 100 degrees C and low shear rates. Shear stability and low shear rate viscosity measurements did not permit adequate assessment of engine oil shear stability. It was found that temporary viscosity losses can be larger than permanent viscosity losses and can be more dominant in determining engine viscosity, that temperature effects on polymer thickening ratio are important in determining engine oil viscosity, and that permanent and temporary viscosity losses in the DISST and comparable mechanical shear stability tests have promise as a means of evaluating the shear stability of oils under conditions similar to those in the engine. Additional information on test procedures and results is appended.

DURABILITY OF DECORATIVE ELECTROPLA
PLASTICS FOR EXTERIOR AUTOMOTIVE USI
REVIEW

Interrelationships among resin, part design, molding p
preplate process, and electroplate structure are addresse
their effect on the part durability of electroplated pla
exterior automotive environments. The expanded use of e
plated plastics calls for a review of technology to avoid
plication, improper design, and unrealistic or inadequa
specifications. Electroplating of plastic parts generally in
tensile strength, elastic modulus, flexural strength, and h
tortion temperature and reduces the coefficient of ther
pansion for the resulting composite. Ductility, measured
sile elongation, and impact strength of the composite are
ly reduced. Resistance of plastic to ultraviolet-induced
and abrasion is dramatically improved with electroplati
metal deposits become thicker, load-bearing properties
composite become more like those of metal. Properly
electroplated plastics produce lightweight, complex, lo
and durable parts, with a lustrous chromium finish that en
the appeal and marketability of automobiles. Plastic resin
cal and tensile properties, resin thermal cycle perfor
molding machines and conditions, behavior of the metal-
bond, catalysis and metal deposition, effect of metal pro
on part durability, chemical properties of metals, and ch
reactivity of the electroplate are detailed.

FOUR STEPS FOR VEHICLE RIDE IMPROVEMENT

Advanced testing and analysis techniques to improve vehicle vibration performance are considered, with reference to modal analysis and building block technology based on minicomputer software, developed by Structural Dynamics Res. Corp. Narrow band spectrum analysis, modal testing, and building block simulation are widely used by the automotive industry for vehicle ride improvement. A four-step procedure being employed on the DeLorean luxury sports car is proposed to enhance the vibration performance of prototype and/or production vehicles. The procedure includes operating (road) tests, artificial excitation tests, modal analysis, and system design analysis. Examples of the procedure's application show how test engineers can identify and evaluate solutions to vehicle vibration problems using a minicomputer-based hardware-software system in the laboratory. Photographs, illustrations, and test data are included.

PARAMETER ESTIMATION TECHNIQUES FOR MODAL ANALYSIS

Parameter estimation techniques are presented that can be used to determine modal parameters (frequency, damping, and mode shape) from experimentally-measured frequency response or unit impulse response. The methods are separated into two categories: curve fit of only one degree of freedom, with or without residuals; and curve fit of multiple degrees of freedom, with or without residuals. Parameter estimation algorithms for determining a structure's modal characteristics are given. Particular attention is paid to multiple degree of freedom techniques utilizing a complex exponential algorithm. Limitations of parameter estimation techniques are noted.

LIGHT DUTY AUTOMOTIVE FUEL ECONOMY....TRENDS THROUGH 1979

Data on the 1979 automotive fleet's fuel economy are presented and compared with data for the 1978 fleet on the basis of projected sales for those two years. Three Environmental Protection Agency (EPA) fuel economy values are measured: city, highway, and combined city and highway. To evaluate the combined value, data on sales distributions of cars in varied weight classes were obtained for model years 1958 through 1979. Fuel economy data were based on the carbon balance measurement method. Detailed analysis showed that fuel economy of the 1979 fleet was 41.5% better than in 1974; 23.2% of this improvement derived from technology advancements and the rest came from weight mix improvements. From 1978 to 1979, there was a 2.8% net gain in fleet mpg, with engine mix and weight mix shifts contributing a 5.2% increase and system optimization a 2.3% loss. About half of the loss appeared related to 1979 changes in dynomometer road load settings. The fuel economy of California cars improved in 1979 at the fleet level. In general, average vehicle interior volume was not sacrificed for fuel economy gains. The achievement of mpg standards promulgated by the EPA through 1985 appears feasible with gasoline-powered vehicle technology and low sales fractions for diesel-powered vehicles. Data on sales of passenger cars and light-duty trucks are appended.

IN-SERVICE FUEL ECONOMY

In a Ford Motor Co. survey of management personnel who drive company-leased vehicles, in-service fuel economy data were computed on approximately 10,600 cars from the 1978 model year. Winter and summer surveys were conducted, and relationships and trends in fuel economy data were analyzed. Results showed that the ranking of different cars by Environmental Protection Agency (EPA) urban, highway, and metro highway fuel economy ratings compares well with Ford's in-service fuel economy rankings. The percentage difference between in-service and ratings developed by the EPA is relatively constant with the level. The difference is also relatively constant for different vehicle classes. A wide range of fuel economies is indicated for each car line-engine-transmission combination, reflecting a wide range of driving habits and operating conditions. In-service fuel economies of cars with manual transmissions are somewhat closer to EPA ratings than cars with automatic transmissions. No significant trend by car size class is demonstrated in the relation between in-service fuel economy and metro highway fuel economy ratings. Survey data are tabulated.

ORIGIN AND STATUS OF THE DOE (DEPARTMENT OF ENERGY) HEAT EXCHANGER TECHNOLOGY PROGRAM TO IMPROVE ENERGY CONVERSION EFFICIENCY

The Dept. of Energy's Heat Exchanger Technology (HET) program and component projects are described. The Energy Res. and Devel. Administration sponsored a 1976 survey to identify deficiencies in HET affecting the development, demonstration, and commercialization of advanced energy recovery and conversion systems. This survey established a need for the HET Program and delineated four types of heat exchanger deficiencies: performance and reliability penalties inflicted by the heat exchanger environment (i.e., fluids in contact with the heat exchanger); design and construction of efficient and reliable high-temperature heat exchangers (material temperatures exceeding 1800 degrees F); poor economics in recovering low-grade waste heat; and lack of information on the long-term performance and reliability of newly-developed heat exchangers. Although HET projects relate directly to coal technology needs, the primary focus is on energy conservation and technology needs appropriate to the Department's Office of Conservation and Solar Applications. Each HET project in the following four categories is described and its progress summarized: environmental effects on heat exchanger performance; high-temperature heat recovery; low-temperature heat recovery; and test/evaluation of improved heat exchangers.

IMPACT OF EMISSION STANDARDS ON FUEL ECONOMY AND CONSUMER ATTRIBUTES

Based on data generated by Volkswagen (VW) this paper reports on the special aspect of the impact which emission standards have on fuel economy and consumer attributes. It was found that the engineering goal to meet 1981 Federal emission standards would have to be 0.2, 1.7, and 0.25 gpm for hydrocarbons, carbon monoxide, and nitrogen oxides, respectively. The engineering goal to meet the 1981 research standard would have to be 0.2, 1.7, and 0.1 gpm. Advanced technology to achieve fuel economy was developed and tested using the VW Rabbit. Consumer attributes of interest were startability and drivability, performance, engine volume and weight, and cost. Introduction of K-Jetronic fuel injection with a closed loop system for compliance with 1981 Federal standards resulted in good economy, low unregulated emissions, low noise emissions, and good driving characteristics (drivability and performance). The fuel injection-closed loop system, however, increased engine cost by 60-70%. Fuel economy deteriorated with the research standard of 0.4 gpm nitrogen oxides.

A FUEL ECONOMY DEVELOPMENT VEHICLE WITH ELECTRONIC PROGRAMMED ENGINE CONTROLS (EPEC)

A vehicle incorporating various fuel economy improvements and an electronically programmed engine control (EPEC) system is described. Fuel economy improvement features combined in this vehicle are road load horsepower (HP) requirement reduction; engine parasitic loss reduction; engine efficiency - emission control system; and automatic transmission loss reduction. Vehicle coast-down tests showed the reduction in road load friction HP requirements on the EPEC vehicle affect the shape of the road load horsepower curve as well as the 50 MPH set point. An electric vehicle dynamometer was required to match these curves at more than one speed. The total EPEC system provided a fuel economy improvement of 12.5% over the baseline comparison vehicle on the combined city and highway tests while also meeting the lower 1981 emission lev
low mileage. Fuel economy benefits of the combined s
and individual components are evaluated.

IDENTIFICATION, QUANTIFICATION AND REDUCTION OF SOURCES OF VARIABILITY I VEHICLE EMISSIONS AND FUEL ECONOMY MEASUREMENTS

Sources of variability in vehicle exhaust emission and fuel
omy measurements were studied in an extensive test pr
conducted by Ford Motor Co. The test program was de
using four vehicles on five CTE-50 Clayton Dynomo
cells. Four repeats for each vehicle-cell combination wer
vided, for a total of 80 CVS-C/H emission and fuel ec
tests. During testing, 23 variables were monitored and re
in real time. Nine other variables were also observed, for
of 32 variables (5 vehicle-related, 16 engine-related, 4 dy
meter, 3 driver-related, and 4 environment variables). The
sion deterioration factor, defined as the ratio between the
sion level of a given vehicle system at 50,000 miles to
4,000 miles, was analyzed. Selective enforcement audit, ce
tion, and correlation tests were performed. The vehicle
major contributor to emission variability while dynamo
driver, and gas analyzer seemed to be more important
economy variability. Instruments developed for on-line d
cording, software for off-line data processing, and sta
analysis techniques used to identify and quantify sour
variation are described. Benefits resulting from reduce
variability are discussed, i.e., lower test cost due to im
test efficiency and increased confidence in results. Data
drocarbon, carbon monxide, and nitrogen oxide emissio
presented.

AN ANALYSIS AND EVALUATION OF THE SELECTIVE TRAFFIC ENFORCEMENT PROGRAM IN AMERICAN SAMOA

The relationship was investigated among four dependent and seven independent variables reflecting the accident problem in American Samoa between July 1974 and April 1977, in order to isolate effects of the Selective Traffic Enforcement Program (STEP) and its impact on the number of accidents. Dependent variables were the number of traffic fatalities, accidents, injury accidents, and injuries resulting from traffic accidents. Independent variables included the number of citations issued, inches of rainfall, gasoline sales, alcohol sales, traffic violation convictions, and overall effect of time (in months). Statistical analysis was employed to analyze relationships among variables. Variables correlating to accidents and STEP at the 0.05 level of significance were subjected to stepwise regression analysis. With accidents as the dependent variable, four potentially significant independent variables were quantified from correlation analysis: alcohol sales; STEP; time; and publicizing names of persons convicted of traffic violations. Subsequent regression analysis revealed that the STEP did not significantly affect accident reduction. Time had a strong impact on accidents, as well as the "publication" variable. Additional study is recommended focusing on more variables and the question of whether to classify American Samoa as a developing country. Also recommended is an extension of the study period and an investigation of accident patterns in areas with cultural and economic conditions similar to American Samoa. A review of related literature is included, and supplementary data are appended.

EPA (ENVIRONMENTAL PROTECTION AGENCY): HEADED FOR TROUBLE ON TRUCKS AND CARS

Automobile and truck engine emission standards proposed by the Environmental Protection Agency (EPA) are criticized. Already in violation of the Clean Air Act, EPA is proposing carbon monoxide (CO), hydrocarbons, and nitrogen oxides standards that will be impossible to meet. According to the Motor Vehicle Manufacturers Assoc., new selective enforcement audit regulations are more stringent for trucks than for cars. Ford and General Motors are working to meet existing standards but with little success. General Motors estimates that meeting the CO standard will increase the price of cars by $30 to $40. EPA's proposed standards for diesel-powered cars and light-duty trucks are 0.6 gpm in 1981 and 0.2 gpm for 1983 and beyond. Many government and industry officials feel that EPA is not addressing the ambient air quality issue or evaluating the economic cost of proposed emission standards.

NEW AND IMPROVED ELASTOMERS FOR AUTOMOTIVE USES

Future requirements for modified polymers to meet automotive design needs are outlined. Two particularly important properties of synthetic rubber are heat and oil-solvent resistance. These properties are primarily needed in automotive applications under the hood, i.e., engine compartment, drive train system, fuel, and emission systems. Most of the new elastomers and improved polymers are designed to improve these properties while maintaining tensile strength, abrasion resistance, low temperature flexibility, and elongation. Constant elastomer upgrading is reflected in Viton fluorocarbon elastomers, which are becoming the elastomer of choice in the fuel system where low vapor permeability, "sour" fuel resistance, and the ability to tolerate gasoline-alcohol blends (gasohol) are becoming critical. Improved polyacrylates with new cure technology are being introduced that exhibit a better compression set and better heat resistance over previous polymers. Dow Corning has announced a high vinyl silicone with improved toughness and flex life for automotive sealing applications. New candidate polymers introduced by the synthetic rubber industry include Norsorex PNR, manufactured in Europe and introduced in the United States by American Cyanamid; F-70 vulcanizable elastomer introduced by American Cyanamid; Vamac, an ethylene/acrylic elastomer marketed by DuPont; two fluoroelastomers, Kalrez and Firestone's PNF 200 phosphonitrile; and a thermoplastic copolyester know as Hytrel.

ELASTOMERS IN DETROIT: STATE OF THE ART, 1980. SPECIAL REPORT

The role of elastomers in the automotive industry's vehicle weight reduction program is considered. The mandate for improved fuel efficiency, pressures for improved damageability and occupant safety, the need to comply with emission regulations, and the desire to provide consumers with a "big car ride" are causing conflict in Detroit. The automotive industry must play a major role in vehicle weight reduction. Weight reductions to achieve an auto fuel efficiency of 27.5 mph by 1985 will center on replacing traditional construction materials with lightweight substitutes such as elastomers. Steel, zinc, and ferrous castings will give way to polymeric replacements. General Motors engineers expect the plastic content of vehicles to increase from 175 lb/car in 1978 to 225-300 lb/car by 1985. Trends in the use of elastomers are reviewed (sheet molding compound, reaction injection molding, reinforced reaction injection molding, adhesive bonding, and tire sealing). Experimental work on the use of carbon fiber (graphite) reinforcement for auto parts is reported and the use of elastomers by Ford and General Motors is discussed. Attached are chronological tables of elastomers' automotive introduction (1968-1977), and estimated plastic usage (1975-1985) by type.

HIGH PERFORMANCE NITRILE RUBBER AUTOMOTIVE FUEL HOSE

General Motors is the first automotive manufacturer to issue an improved performance fuel hose specification. The GM-6165M specification requires a heat-resistant nitrile rubber (NBR) tube with polyester cord reinforcement and a chlorosulfonated polyethylene jacket. Compounding techniques were explored in order to develop an NBR hose that would meet performance requirements of the specification. A 28% acrylonitrile bound antioxidant NBR was used, filled with a low-sulfur zinc oxide-activated cure system. It was determined that expensive and potentially toxic cure additives such as cadmium oxide are feasible but not recommended. Testing of the fuel hose involved heat aging, plasticizer screening, and sour gasoline performance evaluation. Results showed the GM-6165M specification significantly upgrades the performance of NBR-based automotive fuel hoses.

ACTIVITY SPACES AND TRAVEL BEHAVIOR ON A COLLEGE CAMPUS

Activity spaces and related travel behavior of four campus groups at the University of Illinois (Urbana-Champaign) were studied. Of 2,127 travel diary forms returned in the fall of 1974, 2,007 were complete enough for data analysis, which determined that 66% of all moves were on foot, 15% on bicycle, and 19% by automobile. Four aspects of travel behavior (number of trips, trip length, trip mode, and trip purpose) were examined using four campus groups (lower division students, upper division students, graduate students, and faculty-staff). It was hypothesized that travel behavior and activity spaces would vary significantly among these groups due to different residency requirements, access to automobiles, work and class schedules, and time budgeting for nonessential activities. Significant and consistent differences were observed among the groups. Activity spaces and travel options were severely constrained by work and class schedules. Changes in class breaks, class schedules, and use of major travel routes were also important. The study resulted in specific suggestions to ease local conflicts and congestion (specific routing suggestions for certain intersections, closing of some streets to motor vehicles, reallocation of classes to underused buildings, and additional bicycle parking facilities), and general suggestions to reduce overall traffic confusion (changing class schedules, staggering work hours, separating on- and off-campus traffic, extending bicycle network). The effort of university administrators to lessen dependence on automobiles is noted. Activity space and travel behavior models are discussed.

FORECASTING AUTOMOBILE FLEET FUEL EFFICIENCY

A modeling procedure is presented which, when combined with an appropriate macroeconomic simulation model, provides accurate projections of the automobile population by model year, automobile survival rates, and average annual automobile fleet fuel efficiencies. In forecasting fuel efficiency, the modeling procedure considers impacts of prevailing economic conditions, governmental policy decisions regarding new vehicle fuel efficiency standards, and automobile usage characteristics. Major components in determining the number of automobiles in use by model year are new car sales, automobile ownership and automobile survival rates. Fuel efficiency calculations show a 35% increase during the 1979-1990 period. Average fuel efficiencies, if combined with stabilized automobile usage, will generate a significant reduction in total highway fuel consumption.

THE EFFECTS OF PRIMARY POWER TRANSMISSION LINES ON THE PERFORMANCE OF LORAN -C RECEIVERS IN EXPERIMENTAL TERRESTRIAL APPLICATIONS. FINAL REPORT

Tests were conducted to measure the effect generated by high-voltage transmission lines with and without supervisory carrier signals on the performance of typical LORAN-C receivers having potential use in land vehicle applications. LORAN-C is a highly accurate ratio-navigation system originally developed for the Department of Defense and subsequently designated for marine use in the coastal and confluence zone. Tests were performed on high-voltage transmission line configurations owned and operated by the Tennessee Valley Authority. Transmission lines were assessed with 60 Hz power impressed and absent and carrier signals impressed and absent. Data were plotted for three secondary time differences along the East Coast. Signal-to-noise ratios for secondaries as well as the master were recorded. The test area had extremely good LORAN-C signal coverage. With the carrier off and the line de-energized, acceptable receiver performance was obtained to within approximatey 100 meters from the line center. With the line energized, usable performance degraded to a point about 200 meters. With asynchronous carrier signals, performance was unreliable at distances less than about 300 meters. Receivers would not operate properly at 1,000 meters either side of the line with synchronous interference. Test data and the LORAN-C receiver test data sheet are appended.

ANALYSIS OF WEEKDAY, WEEKEND, AND HOLIDAY ACCIDENT FREQUENCIES. INTERIM REPORT

Accident statistics for weekday, weekend, and holiday periods for the 1973-1976 period were analyzed by the Kentucky Dept. of Transportation's Div. of Res. Accident rates were computed for the rural highway system and its three major components: two-lane and three-lane roads; four-lane roads; and expressways (interstate highways, parkways, and toll roads). On rural roads, the largest numbers of accidents occurred on Saturdays, Fridays, and Sundays, respectively. Tuesdays generally had the lowest number of accidents. Highest accident rates for two-lane roads were on Sundays and Saturdays, and rates for expressways were highest on Sundays. Accident rates on weekends were substantially higher than on weekdays. Rates for fatal and all accidents were lower during holiday periods than during weekends not involving holidays. Holiday periods had fewer accidents per day than weekends but had more accidents per day than weekdays. Traffic during holidays, however, was significantly greater than on weekends or weekdays.

A CRITICAL LITERATURE REVIEW OF THE PROBLEM DRINKING BEHAVIOR IN SPECIAL POPULATION GROUPS. VOL. 1, EXECUTIVE SUMMARY FINAL REPORT

A three-part critical review of literature concerning problem drinking behavior in special population groups is summarized. A nine-step research strategy was developed to identify, locate, and assess the needs of special population groups in order to improve delivery of alcoholism treatment and prevention services. A general survey and bibliography of literature associated with the problem drinking behavior of special population groups was compiled. Particular attention is paid to the Spanish-speaking population group. Other major headings in the population group typology are general, institutionalized, ethnic/racial/religious, black, Native American, socioeconomic status, occupation, age (youth, elderly), family, and female. The literature encompasses studies published from 1965-1977.

A RESEARCH STRATEGY FOR REVIEWING THE PROBLEM DRINKING BEHAVIOR LITERATURE ASSOCIATED WITH SPECIAL POPULATION GROUPS. VOL. 2. FINAL REPORT

A research strategy is described for a critical review of the literature on the improvement of alcoholism treatment and prevention service delivery to persons within special population groups who have drinking problems. Nine steps comprise the strategy: identify population groups; locate population groups; determine the extent of problem drinking within special groups; determine treatability and preventability aspects of problem drinking with special population groups; designate high-priority service delivery targets; designate high-priority research targets; designate low-priority service delivery targets; designate low-priority research targets; and identify intermediate priority service delivery and research targets. Overall, the research strategy specifies an approach to organizing information about special population groups, their drinking characteristics, and the nature of treatment-prevention services.

UNLEADED GASOLINE SHORTAGES AND FUEL SWITCHING. THE POTENTIAL IMPACT IN SOUTHERN CALIFORNIA

The impact is assessed of fuel switching (from unleaded to leaded in catalytic converter-equipped vehicles) on increased photochemical smog levels observed in the South Coast Air Basin (SOCAB) of California. The use of leaded gasoline in automobiles equipped with catalytic converters deactivates the converters and leads to increased reactive hydocarbon emissions. A consistent long-term improvement in SOCAB ozone levels, much of which can be attributed to automobile emission controls, was reversed in the summer of 1978. The reversal was determined by data obtained for the Los Angeles basic portion of the SOCAB, adjusted for weather variations. Causes of misfueling were evaluated (shortage of unleaded gasoline due to high demands and low supplies, price differentials between leaded and unleaded gasoline, and performance degradation). Effects of misfueling on the ozone air quality were studied, as well as the effect of increased reactive hydrocarbon emissions on ozone concentrations. It was determined that the air quality in Southern California is being threatened by fuel switching. Economic, legislative, educational, and policy actions to avoid adverse impacts on public health and the economy are recommended.

AN ANALYSIS OF THE AUTOMOBILE MARKET: MODELING OF THE LONG-RUN DETERMINANTS OF THE DEMAND FOR AUTOMOBILES. VOL. 3--APPENDICES TO THE WHARTON E.F.A. (ECONOMETRIC FORECASTING ASSOCIATES) AUTOMOBILE DEMAND MODEL. FINAL REPORT

Documentation of data sources and methodology, a discussion of model equations, and exogenous assumptions are provided for the Wharton Automobile Demand Model which provides long-run policy analysis and forecasting of annual trends for U.S. auto stock, new sales, and their composition by auto-size class. The documentation of data sources and methods includes an overview of the data base, sources for basic data series, and size class definitions and methodology for determining model estimation data. The model equations include a review of the basic structure, cross-section equation estimates, translation to time-series, and time-series equation estimates (new registrations and scrappage, vehicle miles travelled, mpg, new and used car prices, and income distribution). All exogenous input data (demographic, economic, auto characteristic) used for baseline forecasts is presented, together with an indication of sources and methods used in their preparation.

AUTOMOBILE INSPECTION, MAINTENANCE AND REPAIR CONFERENCE PROCEEDINGS. WASHINGTON, D.C., MAY 22-24, 1979

Reports from a three-day workshop on automotive repair and maintenance practices include opening and closing remarks; formal presentations on current Federal auto inspection, maintenance, and repair (IMR) programs; IMR issue papers; workshop sessions; and minority reports (i.e. written comments submitted on issues not addressed or felt to be inadequately considered at conference). Minor editing facilitated a comprehensive transcript of proceedings. Conference attendees (representing government, consumer groups, and industry) participated on one of five panels: standardization, equipment, inspection/diagnosis, consumer and self-help programs, and auto mechanic training. Each panel developed a list of five or more priority programs to be presented at the final working session. A priority ranking of the proposed programs by all participants indicated that programs directed at the auto mechanic and the consumer offer the greatest potential for resolving IMR problems. Several consumer panelists criticized apparent industry domination in the ranking process.

ACCIDENT INVESTIGATION STUDIES IN CONJUNCTION WITH FMVSS (FEDERAL MOTOR VEHICLE SAFETY STANDARD) 301 COMPLIANCE TESTING. FINAL REPORT

A total of forty-five 1978 model year vehicles (passenger cars, pickups, multipurpose vehicles, and vans) were crash tested according to Federal Motor Vehicle Safety Standard No. 301 requirements. Each vehicle was subjected to one of two test modes: frontal impact into a fixed barrier at 29.4 plus/minus 0.5 mph, or rear impact by a 4000-lb moving barrier at 29.4 plus/minus 0.5 mph. The vehicle types, their test date and test mode are tabulated. Data for each vehicle are presented separately, including documentation of trajectory, residual crush, and tire marks. Representative post-test photographs of each vehicle are included.

OLDSMOBILE OMEGA X-BODY BASELINE WEIGHT DATA. FINAL REPORT

A teardown study of the 1979 Oldsmobile Omega X-Body 4-Door Sedan was conducted to provide baseline data for the National Hwy. Traffic Safety Administration on material use, structure, and weight. The data will facilitate the assessment of the future potential of material substitution to achieve weight reduction and accompanying fuel economy improvement. The vehicle model has a 2.8-Litre, V-6 engine and an automatic 3-speed transaxle (front-wheel drive) transmission. A complete weight summary of the major vehicle components, a material distribution list, and photographs of the vehicle and engine-transmission-suspension assembly are provided. Parts lists are provided for the following assemblies: body, frame, front suspension, rear suspension, brakes, engine, transaxle assembly, fuel and exhaust system, steering system, wheels and tires, chassis electrical, cooling system, and bumpers and miscellaneous. Information in these lists includes component description, quantity per car, total weight per car, material description, method of fabrication, gauge thickness, and method of attachment. Photographs of major parts follow each list. Measurements are provided of selected body sections.

PERFORMANCE CHARACTERISTICS OF 197
CHRYSLER 318 CID (CUBIC INCH
DISPLACEMENT) ENGINE. FINAL REPORT

Experimental data were obtained in dynamometer test
cylinder spark ignition 1977 Chrysler 318 CID (cu-in
ment) engine with a catalytic converter, exhaust gas
tion, manifold preheated air inlet system, alternato
only, no output) exhaust gas aspirator, and fan. The
equipped is intended for use in a 49-state (Federal) veh
automatic transmission. The testing was designed
engine performance data for estimating fuel consum
emissions (carbon monoxide, hydrocarbons, and nitrog
for varied engine service and duty and to provide ba
characteristic data required for the Transportation
Center Vehicle Simulator (VEHSIM) computer progr
report and discussion of results are followed by ta
graphical summaries of engine map data.

CONSUMER ADVISORIES OF THE NATION
HIGHWAY TRAFFIC SAFETY ADMINISTRA
1970-1979, WITH INDEX

During the period 1970-1979, the National Hwy. Traf
Administration issued over 180 news releases of speci
to consumers. These "consumer advisories" provided
tion with potential life-saving effect for the drivin
Motor vehicle and automotive product recalls, defects,
ards were announced. These releases are compiled
reference, in ascending order by date. A subject ind
vided (advisories referred to by date and number).

VEHICLE DESIGN IS THE KEY TO LOW CO
MAINTENANCE AND REPAIR

Many maintenance and repair items can be virtually
through proper automotive design and construction (e
batteries that do not require addition of water, self
brakes). Better designs of automatic transmissions and
little or no service over vehicle life. Designs can in
diagnostic systems (e.g. brake warning light, service
systems) or can allow easy inspection (e.g. clear pla
voirs for brake fluid). By making inspection and
simple, car owners can judge whether repairs have
satisfactorily or they can do their own servicing. Dia
maintenance should be made as simple as possible to r
and improve accuracy. By standardizing diagnostic ho
functions, the instrument industry will be encouraged
and build better equipment. A good maintenance ap
the owner-maintenance guide and simplified maintena
dures provided by some automakers with their subcom

July 31, 1980 **HS-810 366**

A new car design should minimize the requirement for special tools. Cars should also be designed to minimize damage in crashes, primarily low-speed ones (e.g. improved bumpers). Expensive mechanical components (e.g. drivetrain) should be mounted so as to reduce the likelihood of damage; body panels should be made in parts to reduce post-crash repair work. Cars should be designed so that crash damage is easy and inexpensive to repair (e.g. General Motors X-body car). The servicing of one component should not require the removal of unrelated components, and parts requiring servicing should be protected from corrosion. Service bulletins and "secret" warranty information should be made available to independent garages, as well as to dealers. The consumer should be provided information that will enable him to judge the repairability of cars.

EVALUATION

AN ANALYSIS AND EVALUATION OF THE SELECTIVE TRAFFIC ENFORCEMENT PROGRAM IN AMERICAN SAMOA
HS-027 324

AN EVALUATION OF PICTOGRAPHIC SYMBOLS FOR CONTROLS AND DISPLAYS IN ROAD VEHICLES. FINAL REPORT
HS-027 165

EVALUATION OF BATTERY PERFORMANCE USING COMPUTER CONTROLLED TEST EQUIPMENT
HS-027 242

EVALUATION OF TECHNIQUES FOR WARNING OF SLOW-MOVING VEHICLES AHEAD. FINAL REPORT
HS-027 150

NEW YORK STATE ALCOHOL AND DRUG REHABILITATION PROGRAM. INTERIM EVALUATION
HS-027 268

PROCEDURE FOR THE EVALUATION OF COMPLETED HIGHWAY-SAFETY PROJECTS
HS-027 264

EXCHANGER

ORIGIN AND STATUS OF THE DOE (DEPARTMENT OF ENERGY) HEAT EXCHANGER TECHNOLOGY PROGRAM TO IMPROVE ENERGY CONVERSION EFFICIENCY
HS-027 310

EXECUTIVE

A CRITICAL LITERATURE REVIEW OF THE PROBLEM DRINKING BEHAVIOR IN SPECIAL POPULATION GROUPS. VOL. 1, EXECUTIVE SUMMARY FINAL REPORT
HS-027 335

ASSESSMENT OF TECHNIQUES FOR COST-EFFECTIVENESS OF HIGHWAY ACCIDENT COUNTERMEASURES. EXECUTIVE SUMMARY. FINAL REPORT
HS-027 151

SAFETY ASPECTS OF CURB PARKING. EXECUTIVE SUMMARY. FINAL REPORT
HS-027 158

SERVICE AND METHODS DEMONSTRATION PROGRAM. ANNUAL REPORT. EXECUTIVE SUMMARY (URBAN MASS TRANSPORTATION ADMINISTRATION)
HS-027 138

EXHAUST
EXHAUST EMISSIONS FROM VEHICLES IN DEMAND-RESPONSIVE SERVICE
HS-027 255

TURBOCHARGING WITH THERMAL REACTOR, EGR (EXHAUST GAS RECIRCULATION) AND ALCOHOL-GASOLINE MIXTURES
HS-027 280

EXPERIMENTAL
THE EFFECTS OF PRIMARY POWER TRANSMISSION LINES ON THE PERFORMANCE OF LORAN -C RECEIVERS IN EXPERIMENTAL TERRESTRIAL APPLICATIONS. FINAL REPORT
HS-027 333

EXPLAINING
EXPLAINING SAFETY HELMET USE BY MOTORCYCLE OPERATORS USING A BEHAVIORAL INTENTION MODEL
HS-027 267

EXTERIOR
DURABILITY OF DECORATIVE ELECTROPLATED PLASTICS FOR EXTERIOR AUTOMOTIVE USE--A REVIEW
HS-027 304

FACTEURS
A FIFTEEN-COUNTRY STUDY OF SOME FACTORS INFLUENCING THE NUMBER AND THE SEVERITY OF ROAD ACCIDENTS. PT. 1. BACKGROUND FACTS AND STATISTICS (UNE ETUDE DANS QUINZE PAYS DE QUELQUES FACTEURS DETERMINANT LE NOMBRE ET LA GRAVITE DES ACCIDENTS DE LA ROUTE. PARTIE 1. DONNEES ET STATISTIQUES DE BASE
HS-027 290

FALL
FALL CAR CARE GUIDE, SERVICE TIPS
HS-027 171

FALSE
THE CRIMINAL USE OF FALSE IDENTIFICATION. A SUMMARY REPORT ON THE NATURE, SCOPE, AND IMPACT OF FALSE ID USE IN THE UNITED STATES WITH RECOMMENDATIONS TO COMBAT THE PROBLEM
HS-027 184

FARMING
HIGH-GRADE FUELS FROM BIOMASS FARMING: POTENTIALS AND CONSTRAINTS
HS-027 289

FAST
DESIGN OF A FAST START GLOW PLUG CONTROL SYSTEM FOR DIESEL ENGINES
HS-027 300

FATAL
ALCOHOL AND OTHER FACTORS IN FATAL MOTORCYCLE COLLISIONS: A PRELIMINARY ANALYSIS
HS-027 175

FATALITIES
HOW WILL DOWNSIZING AFFECT FATALITIES?
HS-027 213

FEDERAL
A COMPENDIUM OF FEDERAL TRANSPORTATION POLICIES AND PROGRAMS
HS-027 254

ACCIDENT INVESTIGATION STUDIES IN CONJUNCTION WITH FMVSS (FEDERAL MOTOR VEHICLE SAFETY STANDARD) 301 COMPLIANCE TESTING. FINAL REPORT
HS-805 206

ENGINEERING THE '80S (AUTOMOTIVE DESIGNS TO MEET FEDERAL STANDARDS)
HS-027 142

FES
A CHARGING SYSTEM FOR THE LI-AL/FES (LITHIUM-ALUMINUM/IRON SULFIDE) ELECTRIC VEHICLE BATTERY
HS-027 244

ADVANCES IN THE DEVELOPMENT OF LI-AL/FES (LITHIUM-ALUMINUM/IRON SULFIDE) CELLS FOR ELECTRIC-AUTOMOBILE BATTERIES
HS-027 243

FIELD
THE EFFECT OF ROAD DESIGN AND MAINTENANCE ON VEHICLE OPERATING COSTS. FIELD RESEARCH IN BRAZIL
HS-027 195

FINANCING
STATE RESOURCES FOR FINANCING TRANSPORTATION PROGRAMS
HS-027 299

FIRE
HIGHWAY ACCIDENT REPORT. CROSS-MEDIAN, MULTIPLE VEHICLE COLLISION AND FIRE, STATE ROUTE 2, NEAR CLEVELAND, OHIO, MAY 6, 1979
HS-027 223

FIXED
HIGHWAY ACCIDENT REPORT. FORD COURIER PICKUP TRUCK, FIXED-OBJECT COLLISION, PATUXENT ROAD NEAR CROFTON, MARYLAND, APRIL 23, 1979
HS-027 266

FLEET
FORECASTING AUTOMOBILE FLEET FUEL EFFICIENCY
HS-027 332

FLYWHEEL
ADVANCED FLYWHEEL ENERGY STORAGE UNIT FOR A HIGH POWER ENERGY SOURCE FOR VEHICULAR USE
HS-027 236

REGENERATIVE FLYWHEEL ENERGY STORAGE SYSTEM
HS-027 229

FMVSS
ACCIDENT INVESTIGATION STUDIES IN CONJUNCTION WITH FMVSS (FEDERAL MOTOR VEHICLE SAFETY STANDARD) 301 COMPLIANCE TESTING. FINAL REPORT
HS-805 206

FOIL

MULTI-FOIL INSULATION CONTAINER FOR ELECTRICAL VEHICLE APPLICATION OF A LITHIUM-ALUMINUM/METAL SULFIDE BATTERY
HS-027 245

FOOD

FUEL FOOD. A GAS-TRONOMIC GUIDE TO OCTANE IMPROVERS
HS-027 145

FORD

HIGHWAY ACCIDENT REPORT. FORD COURIER PICKUP TRUCK, FIXED-OBJECT COLLISION, PATUXENT ROAD NEAR CROFTON, MARYLAND, APRIL 23, 1979
HS-027 266

FORECASTING

AN ANALYSIS OF THE AUTOMOBILE MARKET: MODELING OF THE LONG-RUN DETERMINANTS OF THE DEMAND FOR AUTOMOBILES. VOL. 1--THE WHARTON E.F.A. (ECONOMETRIC FORECASTING ASSOCIATES) AUTOMOBILE DEMAND MODEL. FINAL REPORT
HS-804 847

AN ANALYSIS OF THE AUTOMOBILE MARKET: MODELING OF THE LONG-RUN DETERMINANTS OF THE DEMAND FOR AUTOMOBILES. VOL. 2--SIMULATION ANALYSIS USING THE WHARTON E.F.A. (ECONOMETRIC FORECASTING ASSOCIATES) AUTOMOBILE DEMAND MODEL. FINAL REPORT
HS-804 848

AN ANALYSIS OF THE AUTOMOBILE MARKET: MODELING OF THE LONG-RUN DETERMINANTS OF THE DEMAND FOR AUTOMOBILES. VOL. 3--APPENDICES TO THE WHARTON E.F.A. (ECONOMETRIC FORECASTING ASSOCIATES) AUTOMOBILE DEMAND MODEL. FINAL REPORT
HS-804 855

FORECASTING AUTOMOBILE FLEET FUEL EFFICIENCY
HS-027 332

FORGED

MACHINING STUDIES OF PM (POWDER METAL)-FORGED MATERIALS
HS-027 155

FORMATION

FUEL MOTION AND POLLUTANT FORMATION IN STRATIFIED CHARGE COMBUSTION
HS-027 188

MODEL FOR NITRIC-OXIDE FORMATION IN A LARGE-BORE SPARK GAS ENGINE
HS-027 190

FREE

CURRENT FREE-PISTON STIRLING ENGINE TECHNOLOGY AND APPLICATIONS
HS-027 249

FREQUENCIES

ANALYSIS OF WEEKDAY, WEEKEND, AND HOLIDAY ACCIDENT FREQUENCIES. INTERIM REPORT
HS-027 334

FREQUENCY

AUTOMOBILE INSURANCE LOSSES, PERSONAL INJURY PROTECTION COVERAGES; CLAIM FREQUENCY RESULTS FOR 1977 AND 1978 MODELS
HS-027 163

MECHANISMS OF THE EFFECTS OF VIBRATION FREQUENCY, LEVEL AND DURATION ON CONTINUOUS MANUAL CONTROL PERFORMANCE
HS-027 187

FUEL

A FUEL ECONOMY DEVELOPMENT VEHICLE WITH ELECTRONIC PROGRAMMED ENGINE CONTROLS (EPEC)
HS-027 312

APPLICATIONS OF FUEL CELLS IN TRANSPORTATION
HS-027 234

FORECASTING AUTOMOBILE FLEET FUEL EFFICIENCY
HS-027 332

FUEL CONSUMPTION RELATED TO VEHICLE TYPE AND ROAD CONDITIONS
HS-027 197

FUEL ECONOMY AND EMISSIONS OF LEAN-BURN ENGINES. CONFERENCE REPORT
HS-027 281

FUEL FOOD. A GAS-TRONOMIC GUIDE TO OCTANE IMPROVERS
HS-027 145

FUEL FOR THE FUHRER
HS-027 218

FUEL MOTION AND POLLUTANT FORMATION IN STRATIFIED CHARGE COMBUSTION
HS-027 188

HIGH PERFORMANCE NITRILE RUBBER AUTOMOTIVE FUEL HOSE
HS-027 328

IDENTIFICATION, QUANTIFICATION AND REDUCTION OF SOURCES OF VARIABILITY IN VEHICLE EMISSIONS AND FUEL ECONOMY MEASUREMENTS
HS-027 313

IMPACT OF EMISSION STANDARDS ON FUEL ECONOMY AND CONSUMER ATTRIBUTES
HS-027 311

IN-SERVICE FUEL ECONOMY
HS-027 309

LIGHT DUTY AUTOMOTIVE FUEL ECONOMY....TRENDS THROUGH 1979
HS-027 308

PREDICTING TRAVEL TIME AND FUEL CONSUMPTION FOR VEHICLES ON LOW-VOLUME ROADS
HS-027 198

SPARK IGNITION ENGINE FUEL ECONOMY CONTROL OPTIMIZATION--TECHNIQUES AND PROCEDURES
HS-027 154

SURVEY OF LIQUID HYDROGEN CONTAINER TECHNOLOGY FOR HIGHWAY VEHICLE FUEL SYSTEM APPLICATIONS
HS-027 248

THE BIG SHORTFALL IN AUTO FUEL ECONOMY
HS-027 147

THE EFFECTS OF FUEL COMPOSITION AND FUEL ADDITIVES ON INTAKE SYSTEM DETERGENCY OF JAPANESE AUTOMOBILE ENGINE
HS-027 181

UNLEADED GASOLINE SHORTAGES AND FUEL SWITCHING. THE POTENTIAL IMPACT IN SOUTHERN CALIFORNIA
HS-027 337

WHICH ALCOHOL FUEL FOR BRASIL--METHANOL OR ETHANOL?
HS-027 226

FUELED
PREDICTION OF VEHICLE PERFORMANCE AND ITS SENSITIVITY TO COMPONENT IMPROVEMENTS: APPLICATION TO ELECTRIC AND H2 (HYDROGEN)--FUELED VEHICLES
HS-027 228

FUELS
HIGH-GRADE FUELS FROM BIOMASS FARMING: POTENTIALS AND CONSTRAINTS
HS-027 289

FUHRER
FUEL FOR THE FUHRER
HS-027 218

FUSES
BLADE TYPE FUSES FOR ELECTRICAL CIRCUIT PROTECTION (AUTOMOTIVE APPLICATIONS)
HS-027 157

GADGET
GAS-SAVING GADGET...THAT WORKS
HS-027 219

GAS
AUTOMOTIVE GAS TURBINES: WHERE DO THEY STAND?
HS-027 168

FUEL FOOD. A GAS-TRONOMIC GUIDE TO OCTANE IMPROVERS
HS-027 145

GAS-SAVING GADGET...THAT WORKS
HS-027 219

MODEL FOR NITRIC-OXIDE FORMATION IN A LARGE-BORE SPARK GAS ENGINE
HS-027 190

THE ELECTRONIC GAS WATCHDOG. A UNIT SUITABLE FOR DETECTING THE PRESENCE OF GAS IN A SIGNAL CONTROLLER
HS-027 141

TURBOCHARGING WITH THERMAL REACTOR, EGR (EXHAUST GAS RECIRCULATION) AND ALCOHOL-GASOLINE MIXTURES
HS-027 280

GASKETS
HOW TO CHECK AND REPLACE GASKETS AND SEALS
HS-027 217

GASOHOL
ARGUMENT CLOUDS GASOHOL ISSUE
HS-027 172

IMPROVING OCTANE VALUES OF UNLEADED GASOLINE VIA GASOHOL
HS-027 227

GASOLINE
A NOVEL LABORATORY METHOD FOR EVALUATING INDUCTION SYSTEM DEPOSITS IN GASOLINE ENGINES
HS-027 182

IMPROVING OCTANE VALUES OF UNLEADED GASOLINE VIA GASOHOL
HS-027 227

SOME SPECIAL FEATURES OF THE TURBOCHARGED GASOLINE ENGINE
HS-027 178

TURBOCHARGING WITH THERMAL REACTOR, EGR (EXHAUST GAS RECIRCULATION) AND ALCOHOL-GASOLINE MIXTURES
HS-027 280

UNLEADED GASOLINE SHORTAGES AND FUEL SWITCHING. THE POTENTIAL IMPACT IN SOUTHERN CALIFORNIA
HS-027 337

GLOW

Highway Safety Literature

U.S. Department of Transportation National Highway Traffic Safety Administration

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safety Administration (NHTSA). It is divided into the following sections: Abstract Citations, containing bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-of-context (KWOC) list of words in the title, followed by the full title and HS number (our accession number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Report Number Index. In those months when information on contracts recently awarded is available, a section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technical Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Editor at the address below for inclusion in the collection and abstracting in this publication. Please indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for information. Views expressed are those of the authors and not necessarily those of the Administration. Reference to brand names, equipment, models or companies does not imply endorsement by NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Safety Literature** may be addressed to

Editor

Technical Reference Division
National Highway Traffic Safety Administration
400 7th St. SW
Washington, D.C. 20590

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive Engineers, Dept. HSL, 400 Commonwealth Drive, Warrendale, Pa. 15096. Order by title and SAE report number.

TRB: Transportation Research Board, National Academy of Sciences, 2101 Constitution Ave., N.W., Washington, D.C. 20418.

Corporate author: Inquiries should be addressed to the organization listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED BY MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning the maximum amount of brake pedal force that automobile drivers were able to sustain over a period of ten seconds. Subjects were told to apply the brakes in the test car as they would in a panic stop, and to exert as much force as possible on the pedal over the entire ten second test period. A total of 84 subjects were tested, including 42 males and 42 females. The results indicated that there is a wide distribution of values which characterizes the pedal force that the subjects were able to generate. Male subjects produced generally higher forces than did females. Over half the women tested were unable to exert more than 150 lbs. of force with either foot alone, but when both feet were applied to the pedal, force levels rose significantly.

Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflation pressure are deduced by assuming the bias tire as a composite structure of a bias-laminated, toroidal membrane shell and rigorously taking three displacement components into consideration. The point collocation method is used to solve a derived system of differential equations with variable coefficients. It is found that the lowest natural frequencies calculated for two kinds of bias tire agree well with the corresponding experimental results in a wide range of inflation pressures. Results of the approximate analysis show that the influences of the in-plane inertia forces on natural frequency may be considered small, but the influences of in-plane displacements are large, particularly on the natural frequency of the tire under low inflation pressure.

DISPERSION OF CARBON MONOXIDE FROM ROADWAYS AT LOW WIND SPEEDS

Data from an ongoing model validation program for dispersion of pollutants from roadways in Texas were obtained from experimental sites. A schematic diagram of instrumentation layout at a typical site is shown. These data indicate that pollutant concentrations do not increase as rapidly with decreasing wind speed as predicted by most models which are based on a gaussian formulation. In fact, the actual ground level concentration may decrease with decreasing wind speed when the speed drops below some critical value. A model is needed to predict the dispersion of pollutants from roadways at low wind speeds and stable atmospheric conditions. The line source dispersion model developed by D.P. Chock should serve as a guide to the improvements needed: refining the dispersion parameter, incorporation of buoyant plume rise at low wind speeds, and consideration of traffic induced turbulence. The resulting model may not have the form of the present gaussian expression.

ALL LIT UP: ELECTRONIC BREATH TESTERS SOON

The two conventional breath testers (crystal-filled tube-with-bag) in use by the British police, Alcotest and Alcolyser, are being supplemented experimentally by a new electronic device known as Alcometer SL2. From 1 Dec 1979, it will be used for a year by police in Sussex and West Yorkshire, England. As a control, half the breath tests in each area will be conducted with the old devices. Among the advantages claimed for the Alcometer SL2 are greater accuracy (over the plus/minus 10% accuracy of the old testers), improved readability, and ease and speed of operation. The new device costs 110 pounds, vs. 50 pence for each of the conventional disposable breathalyzers. With the new device, the subject blows into a mouthpiece, and a light on the unit indicates an adequate sample and signals the correct moment to take a reading. The result is displayed on three LED's on the front of the Alcometer: red representing more than 80 mg; red and amber, 70 to 80 mg; amber, 5 to 70 mg; and green, less than 5 mg.

PLASTICS MOVE FROM TOY CARS (TO REAL AUTOMOBILES)

Plastics were introduced in the U.S. automotive industry in the 1950's and today are increasingly attractive in a variety of automotive applications. Although plastics cannot match metal components in the speed of forming or shaping, tremendous progress has been made in its strength, appearance, and versatility. Plastic can often be formed into much more complex shapes in a single operation than metal can. Today, many parts of new cars are made out of plastics (e.g. fenders, panels between body and bumpers, grilles, moldings, interior components). Plastics growth is expected to increase with the 1981 model year, when new body panels and structural components are approved. By the 1981 or 1982 model year, some hoods, deck lids, station wagon tailgates, sliding van doors, and passenger car doors may be made of plastic. Other potential applications include all-plastic car windows, wheels and wheel covers, and fuel tanks. To the automotive industry, plastics promise cost savings, weight reduction, energy conservation, and corrosion resistance. To the car buyer, they offer improved fuel economy, better design, and fewer maintenance problems.

SLASHING AERODYNAMIC DRAG: HOW COMPUTERS REDESIGN A CAR FOR MORE MPG

The design of a unique automobile body shape with an aerodynamic drag coefficient of 0.201 is described. The design, product of collaboration between Alberto Morelli of Turin Polytechnical Univ., Italy, and the Italian auto design firm Pininfarina, is based on a method formulated by Morelli in 1963 for determining the lowest-drag shape for a given volume. Morelli developed a computer program which considered all mechanical components and legal requirements and provided realistic passenger and cargo space with minimum aerodynamic drag. A full-size mockup of the final shape has been constructed, representing a buildable, real-world, four-door sedan, with room for four adults and a reasonable-size trunk. The car has an arched roofline and raised door sills. It has no real hood; the windshield base has been pushed forward almost to the front-wheel axis, and front overhang is minimal. The tail is sharply cut off where the roofline joins the beltline. The drag coefficient of 0.201 translates into a 30% lower fuel consumption at constant 60 mph and at least 15% higher mpg in mixed driving, than the average car. This streamlined shape meets the main design target of low aerodynamic drag, while providing high directional stability.

IDEAL POLICE CAR, 1978 TECHNICAL REPORT, 2ND ED.

Information is provided to assist in the selection of police vehicles to meet the particular needs of the user. Rather than focusing on a single vehicle, the report concentrates on several selected elements, in order to make the reader more aware of current technology, of progress in other cities, and of government research. In a review of the state-of-the-art, the work of a Law Enforcement Standards Lab. is described in which evaluation and testing of police equipment has resulted in several documents on such topics as terms and definitions of patrol cars, economic efficiency, sirens and other warning devices, light systems, radial tires, and life cycling costs. Detailed discussions of police vehicle components include engine, brakes, suspension, tires, interior, and warning system. Compact vs. full-size police vehicles are compared. Information for obtaining police vehicle studies is provided, as well as a list of criteria to be used in writing specifications for an ideal vehicle.

RAMP METERING HELPS SAVE 4.5 MILLION GALLONS OF GAS

The Chicago Area Expressway Surveillance Project is reported on. The system moves more than 250,000 vehicles daily to log 14 million vehicle miles in a 24-hr period. A ramp control procedure begun in 1963 provides 54 stations which operate during the peak periods, keeping entry to the expressway spaced to maintain a steady flow of traffic. The "controller" is located in the surveillance system center; ramp signal changes are transmitted from the central location to the field. Service requirements for all phases of the operation are minimal; the chief maintenance problem is an occasional cabinet knockdown. The effectiveness of the system is significantly increased by the work of the Emergency Patrol, or "Minute Men," 50 men with 39 emergency patrol vehicles and 3 heavy duty wreckers, who are on 24-hr duty to aid stranded motorists. The Patrol is under the jurisdiction of the Illinois Dept. of Transportation, as is the entire traffic control system. Cost for the 105 controlled miles, with 1,600 detectors and over 60 metered ramps, has been less than $8 million. Besides reductions in accidents and congestion, the steady traffic flow provides a reduction in gas consumption estimated at 4.5 million gallons.

FALLING ON DEAF EARS? (NOISE REGULATIONS)

Tighter noise limitations for vehicles will be imposed in the near future, but engineers fear a blanket reduction in legal noise limits would confront car designers with impractically low limits. Sound as measured by instruments differs from what is perceived by the human ear; the difference between a just-audible sound and a deafeningly loud one is best measured on a logarithmic scale, using decibels. Because the human ear is more sensitive to the range 500-5,000 Hertz, a special scale adjustment places more emphasis on frequencies which are heard best; the one used in work with cars is the "A" scale. A daily level of 80dB(A) will not cause appreciable deafness in the average lifetime; the present limit on passenger cars is 84dB(A), and 86dB(A) on large motorcycles. The 92dB(A) limit for heavy goods vehicles with engines over 200bhp is in a range causing partial deafness in from 2 to 20 years. It is feared that if limits are imposed on an all-round basis, by the time trucks are made reasonably quiet, the limitation on passenger cars will be counter-productive. Suppression of sound is more difficult than insulating the environment against it. Putting engines in insulated boxes might cut down external engine noise while increasing noise inside the car and causing weight and heat problems. Economy engines with lower revving rates should generate less engine and possibly less exhaust noise, but higher compression ratios could have the opposite effect. Exhaust noise can be cut, but at the expense of weight, first cost and engine efficiency. The wet grip of tires may suffer if treads are altered to diminish tire noise. Aerodynamic noise may be improved by the lower-drag body designs being considered in the economy drive. The difficulty of locating the exact source of a noise in a vehicle, and deciding how serious it is, leads to disagreement among drivers and engineers. In legislation, a careful balance must be struck between noise reduction and cost as a whole.

A STUDY OF LUBRICATION CHARACTERISTICS ON VALVE STEM SEALS FOR AUTOMOBILE ENGINES

The frictional and controlled oil leakage characteristics of valve stem seals were experimentally investigated by applying the inverse problem of hydrodynamic lubrication, and equations were derived for expressing these characteristics. It was determined that the frictional characteristics of valve stem seals are similar to those of other seals for reciprocating motion (i.e. O-rings, U-seals, and lip-type oil seals). The value of a nondimensional duty parameter at the point the lubrication state changes from hydrodynamic to nonhydrodynamic is closely related to the shape of seal edge and shaft surface roughness. Since controlled-leakage characteristics depend on the contact pressure distribution, the required characteristics can be obtained by varying the pressure distribution.

AM GENERAL/M.A.N. ARTICULATED BUS

An articulated bus is described which was modified from its originally European configuration to comply with all U.S. regulations and specific customer requirements. Detailed descriptions of the bus, its dimensions, performance, and its components are presented, emphasizing the specific aspects of an articulated bus: the underfloor drive train, articulation joint and braking system. The structure, electrical system, interior and air-conditioning system are also outlined and illustrated by photographs and diagrams. As of Nov 1978, approximately 100 buses have been delivered to four U.S. properties and put into revenue service; 300 additional buses are in production for Spring 1979 delivery to seven additional customers.

IMPROVEMENT OF CITYBUS FUEL ECONOMY USING A HYDRAULIC HYBRID PROPULSION SYSTEM--A THEORETICAL AND EXPERIMENTAL STUDY

The application of a hydraulic pump/motor and hydro-pneumatic energy-storage is described as a supplement to the conventional internal combustion engine in a city bus. A mathematical model of a hydraulic hybrid vehicle was developed, based on empirical models of the main components, and used to study potential fuel savings. Three different strategies for controlling the energy flow in the hybrid vehicle according to the actual driving pattern were developed; by appropriate matching of control and strategy and the component sizes used, a fuel saving of 10% to 30% could be obtained. Of the three control strategies, the On-Off Control was preferred to the "Best-Efficiency" Control because it was simpler to apply and gave the same fuel saving potential. It was also preferred to the "Constant Engine Torque" Control Strategy for simplicity reasons. An experiment with a model hydraulic hybrid vehicle, a converted Ford Escort Van, showed that the measured fuel saving (using the On-Off Control strategy) was in close agreement with the theoretical fuel saving calculated with the mathematical model. Mathematical models of the hybrid vehicle components are appended.

CATALYST SYSTEMS WITH AN EMPHASIS ON THREE-WAY CONVERSION AND NOVEL CONCEPTS

The effects accruing from the choice of precious metals and their relative ratios are considered in catalyst systems used in VW and Audi cars under open loop conditions and dynamic closed loop controlled engine conditions in conjunction with an exhaust gas oxygen sensor. The best catalyst system for three-way activity found when comparing major manufacturer technologies was the three-way system Pt/Rh ● 5:1, which was introduced in two 1979 engine families sold in Calif., VW microbus and Audi 5000. Also discussed are the relationship between the selectivity window and the oxygen sensor characteristic, improvements in substrate development, and novel emission control concepts, including metal supported catalysts and catalysed exhaust pipes for the improvement of warm-up. A detailed description of a method of assessing closed loop metering systems is appended.

HS-027 349

A STUDY OF THERMAL ENERGY CONSERVATION IN EXHAUST PIPES

The emissions of hydrocarbons (HC) and carbon monoxide (CO) from a vehicle can be decreased by obtaining faster warmup of the catalytic converter. An experimental study of effective internal insulation of an exhaust pipe has demonstrated a significant increase in converter-inlet gas temperature during warmup, and a lowering of HC and CO emissions on the Federal Test Procedure (FTP) by about 15% on one particular vehicle. Such insulation would be especially beneficial where the temperature of the exhaust gas entering the converter stays very near the catalyst lightoff temperature during the early portions of the FTP. A mathematical model has been developed and verified to predict converter-inlet temperature histories from known exhaust-takedown temperature histories and to quantify the effects of various insulation material properties on the temperature of the gas entering the converter. Agreement is good between the predicted and measured exhaust gas temperatures in uninsulated exhaust pipes and in exhaust pipes internally insulated with either a fibrous moist-pack or a ceramic insulation. The dangers of drawing misleading conclusions from tests of exhaust pipe insulation are discussed.

EXPERIMENTAL ANALYSIS ON EXHAUST GAS TEMPERATURE OF VARIOUS FOUR CYCLE GASOLINE ENGINES

To optimize the design and calibration of an engine, it is important to know the relation between the exhaust gas temperature and the engine parameters. A series of tests were done on six different engines. The engine speed, load, spark timing, air fuel ratio and exhaust gas recirculation ratio were chosen for the calibration parameters, and the compression ratio, valve overlap timing, engine displacement, and number of cylinders were among the design parameters chosen. The data were analyzed statistically and the experimental equation was derived for estimating the exhaust gas temperature. The analytic process is given, with some applications.

HEAT TRANSFER IN THE STRAIGHT SECTION OF AN EXHAUST PORT OF A SPARK IGNITION ENGINE

An experimental system was constructed to study the heat transfer processes in the straight section of the exhaust port of a four-stroke, 325 cc air-cooled two-cylinder spark ignition engine. The effects of engine variables on the steady-state heat transfer rates was studied at four locations in the exhaust port. It was found that the heat transfer rates have a significant dependence on their location within the exhaust port. Data were correlated in the form of a Nusselt-Reynolds number relationship for local and spatially averaged steady-state heat transfer. It is shown that the use of conventional steady-state heat transfer relationships for developing steady-state turbulent flow in pipes predicts heat transfer rates which are lower than those experimentally observed. It was found unnecessary to introduce engine speed parameters into the correlation of time-averaged heat transfer rates, since the results can be correlated using mass flow rate through the engine, independent of engine speed.

INTERIOR NOISE REDUCTION IN A RECREATIONAL VAN

The effect of various acoustic treatments on interior noise levels of a 3/4 ton van was determined. The base vehicle was a 1978 Chevrolet van with a 125-inch wheel base. It was equipped with factory-supplied radial tires and access doors at rear and passenger sides. Noise measurements were conducted under typical highway conditions, with the vehicle in two different running modes. The first test was made with the vehicle idling in drive in a parking lot. The lot surface was asphalt, no reflecting surfaces were close to the vehicle, no exterior noise sources were present, and the engine was operating at a low idle speed. The vehicle was then operated at a constant 55 mph on an interstate highway with a dry concrete surface. Care was taken to insure that passing vehicles did not affect interior noise levels. For all noise measurements, windows were closed, heating and air conditioning fans were off, and extraneous accessories which could rattle were removed. Acoustic levels were determined at the operator's right ear and in the van's rear, three feet above the floor surface and at the rear axle's midpoint. Acoustic materials used in testing were dampers, barriers, and absorbers. Results showed that principal noise sources in a closed van during typical highway conditions are tires and the differential gearbox. This noise is radiated through the vehicle floor into the reverberant van interior. The addition of barrier materials to the floor reduced noise from these sources. A considerable amount of low-frequency noise is probably due to body flexure and resonance caused by the correspondence of van dimensions and the wavelength of low-frequency noise. Absorbing materials reduce this noise by adding absorption at highly-resonant fundamental frequencies. Further reductions in van noise can probably be achieved by using a heavier floor barrier and by increasing low-frequency absorption. A noise reduction of up to 10 dBA was demonstrated for certain barrier and absorber combinations.

TURBOCHARGING FORD'S 2.3 LITER SPARK IGNITION ENGINE

Ford's 2.3-liter turbocharged engine program was designed to develop a system with a 0-60 mph performance capability of 9.4 seconds, to demonstrate the feasibility of turbocharing in an emission and fuel economy environment, and to gain production experience with a turbocharged engine system. The turbocharged engine and powertrain were specifically developed to match the 1979 Mustang and Capri, to provide consumers with excellent vehicle performance and good fuel economy and drivability. After establishing the basic system, certain areas were investigated to optimize engine/vehicle performance: turbocharger sizing and matching; exhaust system; camshaft; axle ratio and transmission gear ratios; fuel requirements; and spark requirements. Ignition system testing to insure reliable operation in a turbocharged environment encompassed reserve voltage capacity, flash-over reliability, radio frequency interference, heat range selection, and spark plug gap selection and maintenance interval. Dynamometer testing was conducted to evaluate the integrity of the basic engine system. Vehicle testing was performed to evaluate the entire powertrain system's integrity and to demonstrate compliance with Environmental Protection Agency emission standards. Durability testing was also conducted. The relatively high compression ratio was retained from the naturally-aspirated engine to preserve low-end manual transmission vehicle performance before turbocharger boost. It is concluded that good turbocharged engine transient response can be achieved by proper design and extensive development work and that the 2.3-liter engine's structural integrity accommodates turbocharged applications with no required revisions to major components (block, cylinder head, crankshaft, and connecting rods). The engine cooling system was modified by a heavy-duty radiator with increased thickness and fin density and a higher capacity fan. Other engine components changed in design or material include a one-piece cast aluminum intake manifold, new cylinder head gasket, intake and exhaust valves, piston and ring package, piston to bore clearance, and the main and connecting rod bearings. A new stainless steel crossover pipe, new downpipe and exhaust gas recirculation tube were added to the exhaust manifold. Fundamentals of basic turbocharing are described and illustrated.

MATHEMATICAL MODELING OF COMBUSTION PROCESS IN A SPARK-IGNITION ENGINE

A model was developed to simulate the combustion process in a spark ignition engine that considers combustion chamber geometry, piston face profile, and spark plug location. One-dimensional unsteady analysis of turbulent flame propagation determined the heat release rate. Chemical kinetic analysis predicted nitric oxide (NO) emission level as a function of time and chamber position, and equilibrium calculation was made of carbon monoxide (CO) emission level at the end of the combustion process. A computer program was established to solve the flame propagation and kinetic equation, with results verified by comparing such experimental data as flame velocity, combustion duration, mass fraction of burned gas versus crank angle, rate of pressure rise, and NO and CO emission levels. Results predicted by the model are in relatively good agreement with experimental results. In a study to investigate the effect of spark plug location on combustion duration, flame velocity, and NO and CO emission levels, it was shown that flame speeds reach a maximum value as the air-fuel ratio is approximately 10% richer than the stoichiometric ratio and that they decrease at higher or lower air-to-fuel ratios. Flame speeds of engines with concentric spark plug locations are faster than those of engines with eccentric spark plug location. NO levels reach a maximum value at an air-fuel approximately 10% leaner than stoichiometric, decreasing at higher or lower values; CO levels tend to decrease with increasing air-fuel ratio, reaching a minimum value at about 0.85 equivalence ratio. It is anticipated that the model will be useful in design studies directed toward improving efficiency and pollution characteristics of internal combustion engines. Supporting equations are appended.

A ONE-DIMENSIONAL COMBUSTION MODEL FOR A DUAL CHAMBER STRATIFIED CHARGE SPARK IGNITION ENGINE

A model has been formulated to simulate combustion in a three-valve stratified-charge spark ignition engine. Conservation equations for mass, momentum, chemical species, and energy are numerically integrated for a one-dimensional flame using an empirical model for turbulent diffusivity. The chemical reaction of fuel and air is modeled using simple kinetics in a one-step reaction, and experimentally determined ignition delays are employed. Nitric oxide emissions are calculated with the aid of a simple Zeldovich model characterized by steady-state atomic nitrogen and equilibrium atomic oxygen. Suggested refinements to the model concern heat transfer; evaluation of chemical kinetics and diffusivity over a wide range of speeds, loads, and nozzle diameters; and ignition delay or flame kernel development. Effects of various assumptions and parameters in the model are discussed, and the model is compared with experimental data from a single-cylinder engine. Conservation equations for the one-dimensional model are appended.

NUMERICAL PREDICTION OF AXISYMMETRIC LAMINAR AND TURBULENT FLOWS IN MOTORED, RECIPROCATING INTERNAL COMBUSTION ENGINES

The flow field in an axisymmetric reciprocating internal combustion engine is calculated as a function of space and time throughout the complete four-stroke cycle. Calculations are based on a procedure that solves governing partial differential equations on a mesh which expands and contracts with piston motion. The importance of intake and exhaust generated turbulence is compared with that of turbulence due to piston motion. Turbulent kinetic energy generated by the piston at the walls is smaller than turbulence generated at the intake. Piston turbulence is caused by the action of shear stress. Compressibility effects appearing in Reynolds stresses, turbulent kinetic energy, and its dissipation rate are small since the mean flow Mach number is small. Numerical results for laminar flow show the formation of a large vortex during the intake stroke. As fluid is compressed, vortex intensity decays and this decay persists throughout most of the expansion stroke. Numerical results for turbulent flow demonstrate that turbulence during the intake stroke is due to shear layers on the sides of the incoming air jet; it is then convected and diffused through the cylinder. Further experimental work is recommended to explore intake and exhaust conditions, unsteady and compressible situations, and heat transfer and temperature profiles. Supporting equations are appended.

PREDICTION OF GAS EXCHANGE PROCESSES IN A SINGLE CYLINDER INTERNAL COMBUSTION ENGINE

Unsteady gas exchange processes in intake and exhaust systems of the internal combustion engine are described. The study of flow dynamics and gas exchange processes leads to better design of exhaust and inlet manifolds, matching and design of pulse-driven turbochargers, and information on catalytic converters and volumetric efficiency improvements. A finite difference scheme is used to solve equations that define intake and exhaust systems. Transient properties, such as pressure, temperature, and velocity, are computed and compared with results obtained using pressure measuring devices and an ultrasonic instrument to record gas temperature and velocity simultaneously. Boundary conditions are fixed by making small approximations with minimal loss in accuracy, resulting in simplified computer programs. Supporting equations are appended.

HYDRAGAS SUSPENSION

Principles of the Hydragas fluid interconnection suspension system are detailed. The essential feature of the system is that car weight is carried by a water-based fluid with no pumps required. The Hydragas unit has a tapered piston which acts through a ball joint. Its arm is pivoted on dual concentric bonded rubber bushes, and a piston supports the diaphragm's inner ring. Diaphragm flexing between piston and skirt forms a fluid seal at the base of the unit. Five benefits of the Hydragas fluid interconnection system are: bigger car ride with the low-pitch frequency, resulting from the interconnection between front and rear wheel stations; constant ride frequencies and damping coefficients regardless of load; car life damping by eliminating conventional shock absorbers; convenience of packaging to maximize trunk space; and elimination of the anti-roll bars. The Hydragas system offers a unique solution to the problems of engineering the suspension for resized (downsized) cars to achieve acceptable ride standards and minimum weight, cost, and packaging, difficulties stemming from the high ratio of load-to-curb weight and the reduced ratio of pitch inertia-to-wheel base. Equations for the mathematical model of the Hydragas system are appended.

DESIGN AND DEVELOPMENT OF AN INDEPENDENT REAR SUSPENSION FOR THE 1979 CADILLAC ELDORADO

The rear suspension design and the vehicle development methodology for the 1979 Cadillac Eldorado are examined. Basic design guidelines were formulated in 1974. These were minimal vertical load couples into the control arm; low static bushing loads; minimal effect on ride of the stabilizer bar and linkage system; and low structural deflection. The level control system is a feature of the vehicle's rear suspension. Its principal components are an air compressor, electronic height sensor, and superlift shock absorbers. A study has been conducted to determine jacking and hoisting compatibility with the independent rear suspension. Provisions have been incorporated to facilitate toe setting at final car assembly and toe adjustment in field service. Static and cycle tests in the laboratory have been conducted to validate design features. Vehicle development is considered in relation to chassis performance characteristics, directional response references, chassis parameter references, subjective factors, specific development activities (spring rate, control arm bushings, stabilizer bar, frame, shock absorbers, and tires), and service factors.

A COMPARISON OF PROJECTED ELECTRIC UTILITY PEAKING GAS TURBINE ENERGY REQUIREMENTS TO POTENTIAL ALCOHOL FUELS AVAILABILITY: 1980-2000

A reasonable commercialization scenario for alcohol fuels production was studied to determine whether it would match projections of electric utility peaking gas turbine fuel demand from 1973 to the year 2000. Estimates of fuel energy requirements were developed and compared to potential alcohol fuels availability. Evaluation was limited to simple-cycle combustion turbines and aircraft-derivative engines. Difficulties in predicting future electric utility peaking gas turbine capacity/fuel requirements were identified as: economic growth (i. e. industrial power demand); population growth (i. e. residential power demand); uncertainty about planning base load power plants (nuclear power plants); future role of electric power use; and utility capital resources (availability of capital for financing large base load plants). With limited information available on the future of alcohol fuels industry development, consideration was given to methanol from coal, methanol from wood (forest products), and ethanol from agricultural crops and residues. It appears that alcohol fuels can provide a significant percentage (45-55%) of energy requirements for electric utility gas turbines as early as 1985 if pursued on a high-priority basis and 100% of projected gas turbine energy requirements could be satisfied by 1987. Economics of alcohol fuels production, especially of optimizing the alcohol fuels production mix, will affect the financial viability of using these fuels for utility peaking turbines. The seasonal production of alcohol fuels and its match with the relatively seasonal use of peaking gas turbines must be considered, as well as the problem of converting fuel delivery and storage systems to handle alcohol fuels. Electricity production costs of alcohol versus conventional fuels in electric utility peaking gas turbines are appended.

PROJECT PLANNING DOCUMENT. HIGHWAY VEHICLE ALTERNATIVE FUELS UTILIZATION PROGRAM (AFUP)

The project planning document for the Dept. of Energy (DOE) Alternative Fuels Utilization Program (AFUP) provides specific criteria and guidelines for evaluating and developing nonpetroleum-based highway vehicle fuels derived from domestic resources. Five distinct alternative fuel categories have related program objectives and well-defined strategies to achieve objectives: new hydrocarbon, alcohol, synthetic gasoline and diesel, and emergency fuels. Problems common to all fuel types are resource availability, conversion technology status, and fuel-engine compatibility. Activity areas critical to alternative fuels development concern process technology assessment, fuel properties and composition, engine-vehicle characterization, and systems studies. Each fuel category is illustrated in a matrix format, and research and development areas to be addressed are noted. A conceptual approach to the ultimate AFUP objective of identifying and implementing an efficient domestic transportation system is described in relation to defined major classes of alternative fuels. Additional information on AFUP projects is appended (current status of projects, budget considerations, and current projects).

FUEL ECONOMY MODELS (FUEL AND FUEL6)

The Automotive Fleet Fuel Consumption Model (FUEL) and the Fuel Economy Projection Program (FUEL6) are discussed, and model documentation is provided. The models are intended to help technical and nontechnical representatives of the National Hwy. Traffic Safety Administration in evaluating, using, and maintaining analytical techniques in fuel economy activities. The FUEL model's basic function is to assess potential fuel conservation benefits resulting from the implementation of hypothetical automotive fuel economy schedules. Input data include historical vehicle registrations and fuel economies (mpg), projected new model year registrations and fuel economies, vehicle survivability and miles traveled by vehicle age, and cash discouting parameters. Output data involve scenario comparisons for projected fleet-fuel economies, fuel consumption savings, fleet size and age, vehicle miles traveled, scrappage, and discounted cash savings. The FUEL6 model's basic function is to calculate the sales-weighted fuel economy for future model year passenger and nonpassenger automobile fleets. Input data concern Environmental Protection Agency fuel economy data by model year and manufacturer, projected percentage improvements due to technology, and penalties associated with regulatory constraints. Output data include data base modifications, engine displacement averages, horsepower-to-inertia weight ratio, fuel economy, and sales fraction as a function of inertia weight and body style. Model documentation includes general information, an engineers' guide, a users' guide, a programmers' guide, and a data element dictionary.

FACTORS INFLUENCING AUTOMOTIVE FUEL DEMAND

Major factors affecting automobile fuel demand trends were analyzed, using a previously-developed light-duty vehicle fleet fuel consumption model. The following factors affecting fuel demand were considered: auto sales; vehicle miles traveled (VMT); scrappage; fuel economy standards; and variance between Environmental Protection Agency (EPA) and on-the-road fuel economy figures. Other factors affecting fuel demand were fuel type, diesel market penetration, and medium/heavy-duty truck fuel consumption. A base case or "best guess" estimate of future fuel demand was developed, and factors influencing fuel demand were varied independently within the range of published estimates for those factors. High and low boundary cases were used to fix the range of possible fuel demand estimates, while conservation and consumption cases were employed to provide realistic alternative estimates of future fuel demand given certain changes in existing vehicle use patterns and fuel economy standards. Uncertainty regarding miles traveled per car and the gap between EPA and on-the-road fuel economy were the most important factors in fuel demand. Automobile scrappage rates also had a significant effect. Variations in light-duty truck registrations had a greater effect on fuel demand than passenger car registrations, due primarily to lower fuel economy levels of light trucks. Under base case assumptions, light-duty vehicle fuel demand is estimated to peak around 1980 at over 104 billion gallons per year and drop about 8% by 1990 before leveling off at about 96 billion gallons per year. Fuel demand in the boundary case ranges from 23% to about 50% below the base case in 1990. More realistic consumption and conservation cases vary from plus 8% to minus 13%, respectively, relative to the base case. This range demonstrates that the potential for reduced fuel demand is higher than the potential for increased demand. With increased conservation efforts, including a 3% reduction in travel, light-duty vehicle fuel demand can be reduced by 0.9 million barrels per day in 1990 below base case estimates. Relaxation of existing fuel economy standards, as shown in the consumption case with no change in travel, can cause an increase of 0.5 million barrels per day in 1990. Narrative and tabular data on automotive fuel demand are appended.

ELECTRIC HYBRID VEHICLE RESEARCH, DEVELOPMENT AND DEMONSTRATION PROGRAM. ENVIRONMENTAL ASSESSMENT

Environmental impacts of the electric and hybrid vehicle (EHV) project established within the Dept. of Energy (DOE) are assessed. The Electric and Hybrid Vehicle Research, Development, and Demonstratioin Act of 1976 (P.L. 94-413) requires a demonstration of 10,000 vehicles over the period from fiscal years 1978-1986, an associated program of financial incentives until fiscal year 1983, and an extensive research and development program. The most detailed portion of the environmental assessment covers first buys of the demonstration project (the number of vehicles demonstrated per year), performance standards, and financial incentives. Later buys and research and development activities are based on available information and reasonable projections. The state of knowledge regarding potential environmental effects of EHV's is rapidly improving as research and development and assessment results become available. Forecasting transportation system impacts is a well-developed discipline. As more information on EHV environmental impacts becomes available, it will be factored into the decisionmaking process. The environmental impact of the EHV demonstration is likely to be insignificant due to its relatively small scale, dispersed operation, and high degree of control. Potential safety and health effects are the most significant, followed by socioeconomic effects. Effects on other environmental systems are negligible. The principal socioeconomic impact concerns the need to train local firefighters near demonstration sites to prevent incorrect procedures in handling electric vehicle accidents. Further data and assessment are needed to evaluate long-term effects of the EHV program on the human environment. Long-range study should focus on materials utilization, physical effects on the environment, occupational safety and health, public safety and health, balance of payments, and cost implications. Further data are also required to resolve the question of hydrogen, arsene, and stibine gas generation during electric vehicle charging cycles. Additional information on EHV research and performance standards is appended.

TOPICS ON CONTAMINATION IN HYDRAULIC SYSTEMS

Topics relevant to hydraulic system analysis were covered at the 1979 SAE off-highway vehicle meeting. The session on "contamination in hydraulic systems" was attended by representatives of educational institutions trade societies, vehicle manufacturers, component suppliers, and related industries. Eight presentations focused on overall efficiency in the first few hours of a pump's life; hydraulic component cleanliness testing (methods and results); agriculture equipment manufacturer's approach to assure a clean hydraulic system; SAE recommended practice J1227 for assessing the cleanliness of hydraulic fluid power components and systems; particle counter physics; significance and preparation of classified test contaminants; multiple location radioactive wear analysis techniques; and ferrographic analysis for hydraulic fluids.

INVESTIGATION OF OVERALL EFFICIENCY IN THE FIRST FEW HOURS OF A PUMP'S LIFE

Eighteen external spur gear pumps supplied by three manufacturers were tested to evaluate changes in overall efficiency during the first few hours of a pump's life and to assess performance characteristics. Pumps were subjected to a common break-in procedure except for variation in oil contamination level. Twelve pumps had clean oil (less than 100 particles/ml contamination), and the remaining pumps contained dirty oil (1500 particles/ml contamination). Results indicated a strong correlation between test stand contamination and roll-off cleanliness. No measurable benefit or liability was associated with contaminated break-in, although the effect of such break-in on life expectancy has yet to be evaluated. Changes in overall efficiency during the first few hours were primarily caused by changes in mechanical rather than volumetric efficiency. It is recommended that any industry standard to collect power conversion data for use in the marketplace require that a pump be broken in and then run at high pressure for about three hours.

HYDRAULIC COMPONENT CLEANLINESS TESTING--METHODS AND RESULTS

Tests were run on hydraulic components of several four-cubic-yard tractor shovels to determine if critical components such as hoses, tubes, cylinders, and reservoirs were damaged during the cleaning process. Liquid automatic particle counting was used to determine component cleanliness in aircraft hydraulic oil and trichloroethane solvent. Test results were put into a computer data base for analysis. The overall contamination level in the hydraulic system was not found high enough to cause excessive damage to critical components. The test methods are relatively simple, reliable, and inexpensive. Computer analysis is an effective tool for studying large amounts of data and identifying pertinent factors. The test program has led to the development of specifications for contamination limits.

AN AGRICULTURE EQUIPMENT MANUFACTURER'S APPROACH TO ASSURE A CLEAN HYDRAULIC SYSTEM

The approach taken by International Harvester to minimize customer downtime and assure a clean hydraulic system required the involvement of design engineering, manufacturing, and relability personnel. A special task force was established to reduce tractor warranty costs associated with hydraulic system failure due to contamination. The problems were found to be based on hydraulic failure from system blockage by visible particles and erosion failure from nonvisible particles. Causes of hydraulic contamination included metal shavings, grey iron, sand, shot, fiber, paint-sealer, sealing compound, miscellaneous dirt (floor), weld splatter, and rust. Six steps were implemented to minimize these causes: to clean rough casting prior to shipment; to flush each casting containing cast-in-tubes with pulsating high-velocity water; to receive hydraulic components at assembly plant in plastic bags, with major audit by inspection in producing plant prior to shipment; to run incoming hydraulic fluid supplied to test stands and fill points through a central filtration unit prior to use; to flush complete hydraulic system of each tractor with clean oil for five minutes, following a 10-minute run cycle; and run each unit for 30 minutes with add-on kidney filters after it has come off the assembly line. Benefits of contamination reduction include lower warranty costs and fewer customer complaints. Methods and procedures to assure compliance with cleanliness specifications are outlined.

STATUS REPORT ON SAE (SOCIETY OF AUTOMOTIVE ENGINEERS) RECOMMENDED PRACTICE J1227--"ASSESSING CLEANLINESS OF HYDRAULIC FLUID POWER COMPONENTS AND SYSTEMS"

The work of the Task Group (roster attached) in developing the SAE Recommended Practice J1227 to assure clean hydraulic components and systems is reviewed. The practice is intended to provide a basis for measuring and reporting cleanliness levels so that built-in contamination and premature failure of hydraulic systems can be minimized. Items to be evaluated are complete systems and integral subsystems, static components (reservoirs, fittings, tubing, filter housings, and manifolds), dynamic components (pumps, motors, cylinders, accumulators, hoses, and valves), parts, and fill hydraulic fluid. Reynolds number is an important consideration. In illustrating the problem of room temperature flushing, it is shown that effective flushing should be done at a turbulent Reynolds number which exceeds the maximum Reynolds number experienced by a system under field conditions. Responses to a ballot reflecting approval/disapproval of the practice are noted.

PARTICLE COUNTER PHYSICS

Physical concepts in the operation of liquid automatic particle counters are addressed. Introduction of automatic liquid particle counter systems has promoted awareness of fluid particulate contamination. Basic measurement principles are similar in systems utilizing light blockage and/or light scattering. A light source is passed through a sensing volume and is incident upon a photodetector. When the sensing volume is devoid of any material (fluid and particulates), output from the photodetector is proportional to the light source intensity. The sensor operates in a two-dimensional reference frame. For a given sensor geometry, flow rate is directly proportional to the photodetector's frequency response. Five conditions should exist for acceptable particulate sizing and counting: the illuminating source should have a narrowband emission spectrum with a peak wavelength below the smallest dimension of the particle to be counted; the photodetector's response curve should peak at or near the same wavelength as the light source and should have a narrow response band; calibration for both size and rate should only be conducted with particles of known geometry which display a uniform area during transit; calibration should not be attempted with contaminant distribution so that deficiencies in the counting system can be isolated; and governing equations based on sensor geometry and response characteristics should not be violated. A critique of the American National Standards Institute Standard B93.28 for the calibration of liquid automatic particle counters is presented.

HS-027 382

THE SIGNIFICANCE AND PREPARATION OF CLASSIFIED TEST CONTAMINANTS

Problems associated with the specification and size characterization of classified test contaminants (CTC's) in the hydraulic industry are examined. Contaminant amount is important in hydraulic system operation, but particle size distribution is even more critical in establishing the tolerance of a hydraulic component to contamination or in determining the degree of filtrating protection required. The location of reservoir breathers, cylinder seals, and filters can affect the amount of contamination encountered by an adjacently positioned component. Particle size distribution can be expressed in a spectrum of curves and mathematical functions which depend on the nature of particle composition and the reference system selected for display, i.e. algebraic, power, or integral functions. Other significant physical properties in CTC formulation include uniformity in specific gravity and particle shape throughout the CTC particle size distribution, chemical properties of classified test contaminants, and relative refractive index of particle solids to the testing fluid. The preparation of CTC's is discussed and the importance of specifications for CTC's in the hydraulic industry is emphasized.

MULTIPLE LOCATION RADIOACTIVE WEAR ANALYSIS TECHNIQUES

A proven radioactive technique is proposed for measuring wear in hydraulic components. The SPI-Wear system, developed by the SPIRE Corporation in Bedford, Mass., uses radioactive tracers only in the area of a wearing surface. Because of the system's selective nature, several areas within a component can be monitored simultaneously. The use of small irradiated areas of wearing surfaces permits the measurement of surface wear from outside the component. Several applications, including aerospace and engine wear evaluations, have successfully employed the system. It is suggested that the technique is appropriate for laboratory wear monitoring, hydraulic system component testing, performance degradation assessment, monitoring of several points within one component, measurement of activated surfaces from which material is being removed, and manufacturing processes. Proposed applications are metallic wearing areas of hydraulic system components, e.g. pumps, motors, valves, and cylinders. The technique can provide a direct relationship between surface wear and component performance degradation.

FERROGRAPHIC ANALYSIS FOR HYDRAULIC FLUIDS

Principles and development aspects of ferrography are explained. Ferrography is a method of particle analysis for fluids, especially wear particle analysis for oil-wetted machine components. Instruments to conduct ferrographic analysis are the direct reading ferrograph which provides information on the concentration and size distribution of fluidborne wear particles, and the analytical ferrograph which is used to prepare a ferrogram which is subsequently examined with a bichromatic microscope. A special microscope is used to examine ferrograms equipped with both reflected and transmitted light sources. Ferrous particles are deposited on a ferrogram according to size because the force acting on a particle is proportional to volume while viscous resistance of the suspending fluid is proportional to surface area. Ferrogram examination in the bichromatic microscope reveals particle size, shape, and quantity details from which the condition of oil-lubricated parts can be assessed. Determining the composition of particles on the ferrogram can establish their origin. Deposition site, reflectivity, and particle color aid in identification. A simple mathematical model is presented to demonstrate how equilibrium particle concentration in machine oil is reached. The application of ferrography to study wear metals and other nonmetallic debris in hydraulic systems is examined. On-line monitoring of machinery rather than periodic sampling is recommended. An on-line ferrograph is currently under development.

WHAT'S YOUR EXCUSE?

Information on the lifesaving potential of lap-type safety belts in accidents is reported. Half of all injury-producing accidents occur at impact speeds of 40 mph or less. Adequate safety belts are on the market, and official design standards include ease of adjustment. The chance of survival in an accident is five times greater if the person stays inside the car. Safety belts prevent ejection, yet thousands of deaths and serious injuries are caused by being thrown from the car, dragged or run over by another vehicle. Safety belts can also help prevent the "second collision," being thrown around inside the vehicle. They can keep an individual from being knocked unconscious. A rollover in a convertible is dangerous with or without safety belts, but only 10% of all serious accidents involve a rollover. Three-fourths of all traffic accidents occur within 25 miles of home, and about one person in four is involved in an accident every year. It is estimated that the use of lap-type safety belts would save at least 12,000 lives annually by preventing ejection from the vehicle and reducing contact with the vehicle interior and other occupants. Reasons for not using seat belts are cited.

FORKLIFTS: TINY TRUCKS, BIG HAZARDS

The safe operation of forklifts is considered, with reference to equipment maintenance and operator precautions. According to a naval instructor of material handling equipment courses, a good starting point for forklift safety precautions is noting warning and data plates often located on the mast and sides of the forklift. Operators should understand and be familiar with these plates, and they should know the basics of forklift maintenance. Going too fast and misusing brakes are common accident causes. Before using a forklift, it is important to look for any hazards that may interfere with work. Rubbish, stacks of supplies, and scattered equipment are often in the way. Broken pallets or pallets without banding straps can produce a damaging spill. Pallets should always be lifted, never pushed or bumped into place. Forklifts should always be equipped with a "headache rack" or overhead guard. Other safety suggestions include testing the brakes, securing the forklift before dismounting, permitting no one but the driver to ride on the machine, using a safety pallet, keeping the forks as low as possible and grounded when standing, and above all, being alert while operating the machine to people who might be in the path.

CONSPICUITY OF MOTORCYCLES

Experiments were conducted to compare the relative benefits of three methods for increasing the detectability of a motorcycle in daylight: increasing brightness of the motorcycle's front using low-beam and high-beam headlights; increasing the motorcycle's frontal area by fitting a white wind fairing to the front; and increasing rider visibility by requiring the rider to wear a high-visibility fluorescent red jacket. The first experiment measured response time for identifying various conspicuity-increasing devices on the motorcycle. The second experiment ascertained the detectability of various signals relative to the basic motorcycle. High-beam headlights significantly increased daytime detectability when compared to low-beam headlight use. Increasing the motorcycle's frontal area and increasing luminance contrast with the riding jacket provided lower daytime detectability than low-beam headlight use against a "cluttered" background. The wind fairing was more detectable than low-beam headlights in a "clean" background environment. It is concluded that signal detection methods provide a sensitive measure of the difference in motorcycle detectability when various visibility-increasing devices are employed, and that all four devices tested improved the daytime detectability of the test motorcycle.

STRONGER FEDERAL DIRECTION NEEDED TO PROMOTE BETTER USE OF PRESENT URBAN TRANSPORTATION SYSTEMS. REPORT TO THE CONGRESS

The effectiveness is evaluated of regulations jointly issued in 1975 by the Federal Hwy. Administration and the Urban Mass Transportation Administration that require urban areas to develop short-range transportation plans. The plans are to represent a coordinated planning process in which automobiles, public transit, taxis, pedestrians, and bicycles are treated as elements of an integrated transportation system. Urban areas are to consider a wide range of projects, such as preferential treatment for transit and other high-occupancy vehicles, progressive timing of traffic signals, and establishment of pricing mechanisms to reduce vehicle use in congested areas. The regulations have resulted in more attention by urban areas to short-range low-cost solutions for transportation problems but have not produced integrated transportation plans or the widespread adoption of projects different from those implemented prior to regulation. The regulations have not been as effective as they could have been for three main reasons: the Federal Hwy. Administration and the Urban Mass Transportation Administration have not enforced the regulations consistently; urban areas have not been able to institute planning processes that culminate in unified plans; and projects with the most potential for improving the efficiency of existing transportation systems have not been widely adopted. The conclusion is that the Secretary of Transportation needs to strengthen Federal administration of regulations.

REGULATING CHRYSLER OUT OF BUSINESS?

The impact of government regulations on the competitive position of the Chrysler Corp. is evaluated. Regulatory requirements that appear uniform and fair may substantially alter the competitive structure of an industry because the burden tends to fall disproportionately on smaller firms. Congress has responded to auto safety, environmental, and energy concerns by passing a law authorizing the Department of Transportation to regulate auto design and manufacture. In assuring compliance with legislative mandates, regulations act as a form of taxation. Expenditures are made by a company to comply in order to stay in business and not in response to demands of the marketplace. The predicament of Chrysler Corp. is an example of unintended effects caused by increasingly more stringent regulations. Regulations reduce opportunities for companies to specialize in providing unique combinations of features to consumers. Since both Chrysler and Ford are smaller than General Motors, they have aimed more at specialized submarkets rather than toward the market as a whole. While it is impossible to predict the long-term impact of regulations, it is clear that fewer motor vehicles will be produced and that automobile users will pay higher prices. The cost of complying with safety, emission, and fuel economy standards is analyzed in some detail.

DESIGN SYNTHESIS OF A VEHICLE SUSPENSION SYSTEM USING MULTI-PARAMETER OPTIMIZATION

The transmission of road-generated vibration into a vehicle body is treated as a source-path-receiver problem. With the suspension system acting as the path, improved isolation can be achieved by having a single compliant bushing at the connecting point of the shock absorber to the body and no bushing at the other end. Better vibration isolation can be attained with smaller stiffness ratio values. An expression for the absolute displacement transmissibility of a vehicle body is derived, and an optimization procedure is applied to analyze values of nondimensional variables. This reduces the maximum motion transmitted to a vehicle body from the road surface over a broad frequency range. Design data show the influence of three variables on transmissibility: bushing stiffness; resonant frequency ratio; and damping coefficient.

VEHICLE RESPONSE TO STOCHASTIC ROADWAYS

A procedure is developed to facilitate dynamic response calculations for vehicles traversing irregular surfaces. The procedure allows direct computation of mean square values and correlations of system variables for both transient and steady-state conditions. It is based on a differential equation for a covariance matrix which is directly related to vehicle state equations. Multiple white noise inputs can be incorporated, as well as inputs at two wheels following the same track at a distance from one another. The procedure is suitable for computer implementation without the complex algebra involved in finding all necessary transfer functions and without the need to evaluate integrals in order to find mean square values using the conventional approach. A simple vehicle model is worked out, and the variation of pitch and heave motion is plotted as a function of vehicle speed.

MOTOR VEHICLE BRAKING SYSTEMS AND COMPONENTS. STANDARDS, RECOMMENDED PRACTICES, INFORMATION REPORTS

Standards and recommended practices promulgated by the Society of Automotive Engineers to address motor vehicle braking systems and components are delineated. The handbook contains tabular, graphical, and narrative information concerning such components as hoses and tubing, seals, gaskets, cylinders, valves, brake fluid, blocks, linings, and shoes. Among the requirements specified are those for nomenclature, labeling, location codes, test procedures, maintenance, and performance of systems.

THE USE OF TELEVISION PUBLICITY TO MODIFY SEAT BELT WEARING BEHAVIOUR

A television publicity program was initiated in Victoria, Australia, to reduce the incidence of injuries related to poor seat belt adjustment, in spite of mandatory seat belt usage. Three target behaviors were chosen for study (degree of tightness, location of buckle, and webbing twist). The program was planned to emphasize benefits of a well-adjusted seat belt. Experiments were conducted to explore the relation between television publicity and behavioral change. Using a criterion measure of change in belt adjustment during roadside surveys, experiments demonstrated that intense exposure to television publicity over a short period significantly decreased the incidence of loosely adjusted belts, buckles located on the abdomen, and twisted belt webbing. Exposure involved three to four screenings per night during peak time on commercial stations for 14 consecutive nights. Other combinations of intensity and duration did not yield consistently positive results. Features contributing to the success of the program included specific target behaviors directly related to injury causation, capable of unambiguous demonstration, and associated with a widespread parent behavior; a message source of high credibility and status, with fear as a motivating factor, and comprising a specific concrete demonstration of target behaviors; and a campaign of short, intense exposure. It was concluded that television publicity was a practical stopgap countermeasure to enhance the longer term solution of redesigning seat belts; that the validity and utility of a limited range of communication principles has been reinforced; and that research can be successfully undertaken to measure the real-world effects of a publicity program.

FITTING AND WEARING OF SEAT BELTS IN AUSTRALIA. THE HISTORY OF A SUCCESSFUL COUNTERMEASURE

The impact of fitting and wearing seat belts on vehicle occupant safety in Australia is addressed. Over 100,000 road users have been killed and 2.2 million persons have been injured since 1925 when road accident data for Australia were first published. Encouraging seat belt use is the focus of major road safety experiments. The Design Rule (DR) system encompasses safety standards for seat belts and anchorages for passenger cars and derivatives. Improvements have been made to seat belt design and wearability through the DR system which requires seat belts in all new vehicles except buses. Compulsory seat belt wearing legislation has been enacted in Victoria. It is estimated that about 4,200 more people would have been killed since the early part of 1971 without this legislation, but additional efforts are necessary. Occupant protection must be further improved through belt system changes and vehicle redesign. Consideration must be given to the effect of usage on belt performance, the effect of enforcement on belt wearing, the role of publicity programs, and improved protection for younger car occupants. Additional information on restraint systems, vehicle safety, and seat belt legislation is appended.

TRANSPORT FOR THE ELDERLY AND THE HANDICAPPED--AN OVERVIEW FROM THE LATE 70'S

Accessibility and mobility problems of the transport-disadvantaged are addressed, particularly those of elderly and handicapped persons, and transport policies in the United States, Great Britian, France, and other countries are reviewed. Problems in providing transport for the elderly concern their lifestyle and frailty. The rationale for providing a minimum level of acceptable mobility for the elderly is based on social welfare considerations. The rationale for the handicapped is generally set in both economic and social terms. Seven urban movement options may be open to elderly and handicapped people: walking; conventional public transport; specialized transport; taxis; school buses and postal delivery buses; personal transport; and private systems. There is a general focus on providing relatively high accessibility to the elderly and the handicapped in industrialized countries. The major controversy centers on whether to offer universal accessibility or to limit the cost of modifying and constructing installations and rolling stock and providing special systems for the nonambulatory. The cost of new accessible vehicles or of retrofitting installations and vehicles so they are accessible to the disabled will be high, resulting in higher fares and an accelerating decline in bus usage. These costs would be higher than those of providing special transport services. Certain groups, however, have objected to special services as vulnerable to cut-off in times of financial stringency.

OUR UNEXAMINED AUTOMOBILE CULTURE

The "automobile culture" is examined in relation to the transportation industry's profit motive and the Federal government's ability to regulate the industry in support of public interests. The auto regulatory process is administered by the National Hwy. Traffic Safety Administration (NHTSA), the Federal Hwy. Administration, and the Environmental Protection Agency. Vehicle fuel economy and safety characteristics are regulated by the NHTSA. Public participation in the auto regulatory process is minimal, although citizens pay about $420 billion (in 1978 dollars) per year for mobility. The automobile-truck-highway share of this figure is $352 billion or 83%. Another $100 billion represents societal costs of automotively induced air and water pollution, congestion, accidents, medical expenses, and government subsidies. Much of the transportation industry's influence is based on its mastery and distribution of information. Both auto-highway lobbies and manufacturers conduct extensive public relations and advertising campaigns while the imbalance between public participation and industry interest in the regulatory process is not conducive to meeting transportation needs. Biases in environmental impact statements are discussed, and the importance of seriously regulating the auto industry is stressed.

PEOPLE DOING WHAT THEY DO BEST: THE PROFESSIONAL ENGINEERS AND NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)

The engineering focus of the National Hwy. Traffic Safety Administration (NHTSA) is considered. Factors that can be changed to decrease traffic accidents and deaths include automobile drivers and passengers, vehicles, and the highway environment. Programs to reduce the level of human failure involve driver education, law enforcement assistance, and rehabilitation and treatment of problem drinkers who drive. Efforts to reduce dangers in unsafe vehicles involve Federal Motor Vehicle Safety Standards for individual automobile components. Programs to improve the highway environment center around reducing dangers of the roadside or upgrading the availability and quality of safety resources for motorists. The NHTSA is responsible for stimulating programs to improve these safety resources. The agency's emphasis on crash engineering has encouraged administrators to be independent from the auto industry. Technical viability is a vital condition for any successful safety standard, but political and economic viability in terms of consumer acceptance and protection from unwarranted costs seems equally important. The research emphasis may facilitate technical viability while frustrating political and economic viability. Engineers do not consider economic costs of proposed standards and the appropriate role of the Federal Government in regulating automobile consumers. Of the five NHTSA administrators none has had formal engineering education. The inevitable reaction of most NHTSA personnel to administrator involvement is that he will make a political rather than a professional decision. It is concluded that the NHTSA has not pursued a well-balanced approach to highway safety. Air bag standards promulgated by the agency are noted as a case in point.

CHECKING AND REPAIRING YOUR CAR'S AUTOMATIC CHOKE

Do-it-yourself procedures for checking and repairing various types of automatic choke on automobiles are described and illustrated. An engine's air-fuel mixture must be rich for good cold starting and running, since fuel vapor tends to condense on cold intake passages, leaning out the combustible mixture that actually reaches cylinders. Choking a cold engine produces an air-fuel mixture rich enough to overpower the lean-out tendency. Besides the choke plate, an automatic choke incorporates a thermostatic coil, heating system, and choke-break and dechoke mechanisms. Coil tension significantly affects the air-fuel ratio during engine start-up and warm-up. A choke's heating system warms the thermocoil enough to open the butterfly fully when the engine does not need more choking. Another choke heating system uses exhaust-heated air for warm-up. A remote choke gets its heat directly from contact with the exhaust manifold or intake-manifold exhaust-crossover passage. Some chokes pass hot engine coolant around the choke coil for a fast warm-up, and a few systems use more than one heating method to assure good choking under all conditions. The choke-break mechanism gets the choke plate cracked open as soon as the engine is running to prevent over-choking while the heating system becomes fully actuated. Most choke-breaks are vacuum kicks, pulloffs, or pulldowns. A fourth choke mechanism is the dechoke, choke unloader, or wide-open kick. The carburetor's fast idle works in conjunction with an automatic choke. Owner and shop manuals are useful in choke repair. The difference between too-rich and too-lean engine operation must be recognized. Cold starting problems due to incorrect thermocoil tension adjustment and/or wrong link length on a remote unit must be resolved, as well as cold running problems that result from faulty vacuum kick action.

THE INACCURACIES OF POLICE RADAR: OVERDRIVE'S REPORT

Errors associated with police use of typical police electronic speed measuring devices are identified. The simple pressing of a wrong button on the dash unit can cause radar to see signals it cannot properly decipher, (i.e. incorrectly pressing the stationary mode unit in a moving police car can cause the unit to read the police car's speed rather than the chased car's speed). If the officer fails to change from moving to stationary mode, the unit can misread. If the officer leaves the operation control button in the calibrate position, the unit can erroneously record and lock in the calibrate reading instead of the true speed. The pressing of light test buttons can lock in erroneous speeds as high as 88 mph. Batching occurs when the signal is initially sent out and a speed is incorrectly locked in before the unit has stabilized itself. Panning is another electronic mistake that happens when the officer sweeps or pans the unit from one traffic lane to another in order to catch alleged speeders in other traffic lanes. One of the most common errors is the reading of stray or unwanted electronic signals. The pitch of a whistle, mobile telephones, neon lights, microwave ovens and fluorescent lights, even flying birds, can cause speed readings on radar. A common source of radar misreading is faulty target identification since at 1,000 feet, the radar beam is about 135 feet wide. This fault of radar is that the unit sees and locks onto the largest mass or signal of least resistance, e.g. a truck, which illustrates the unit's built-in discrimination bias in picking out a larger vehicle that may be going slower alongside a faster but smaller vehicle. It has been estimated that radar transmission exposure can cause cataracts of the eyes. Public health hazards of radar, the importance of police thoroughness and honesty, and the effect of unfair radar techniques on police-community relations lead to the conclusion that police radar should probably be banned altogether.

THE EFFECT OF AMBIENT TEMPERATURE VARIATION ON EMISSIONS AND FUEL ECONOMY--AN INTERIM REPORT

Emission and fuel economy data were obtained when 10 dissimilar cars were run using the 1975 Federal Test Procedure (FTP) and Highway Fuel Economy Test Procedures. Two pre-1975 cars and two cars designed to meet future emission standards were included. Remaining cars were 1977 and 1978 models of varying designs. The data was collected to determine how well emission control equipment designed to be effective at normal FTP test temperatures would work at temperatures ranging from zero to 110 degrees F. The influence of air conditioners was also ascertained. Results showed hydrocarbon (HC) and carbon monoxide (CO) emissions were generally higher at low ambient temperatures than at the "normal" FTP temperature of 80 degrees F. The HC and CO emission increases observed at lower temperatures appeared to be a function of vehicle technology. Air conditioner use generally caused a significant increase in HC and CO emissions. Nitrogen oxide emissions were affected by ambient temperature but to a lesser extent than HC and CO emissions. As expected, fuel economy decreased with temperature and with air conditioner use.

ELIMINATING YAW INSTABILITY IN TRACTOR-SEMITRAILERS DURING CORNERING

A two-year Hwy. Safety Res. Inst. study of yaw instability examined the causes and assessed means of eliminating such instability in tractor-semitrailers during cornering. The study was designed to identify maneuver conditions that produce tractor-semitrailer yaw instability; to examine the propensity for unstable yaw in various tractor-semitrailer combinations in use; and to identify primary mechanisms by which design and operating variables combine in tractor-semitrailers to degrade yaw stability. Efforts were also made to modify typical tractor-semitrailers in ways that defeat destabilizing mechanisms and to demonstrate stable performance of modified vehicles in full-scale tests. Based on an analysis of accident records, five tractor types and two semitrailer types were selected for computer simulation study. Design and operating variables included frame stiffness, suspension stiffness, tire mix, fifth wheel placement, and variations in semitrailer loading. Yaw instability during cornering was found to result from fore-aft imbalance in tire side forces. This imbalance on curves was primarily caused by designed-in differences in the roll stiffness of front and rear tractor suspensions. Two experimental modifications of tractors were developed, installed, and tested (frame-stiffening device and a front suspension sway bar). The sway bar, designed to increase the roll stiffness of the front suspension, effectively eliminated yaw instability at levels of lateral acceleration less the rollover threshold. Combinations of design options and operating practices are listed which lower the yaw-instability threshold of a tractor-semitrailer, and suitability of various engineering methods for examining yaw instability are evaluated. Further research is recommended to evaluate the role of yaw divergence in accidents, the design and operating parameters known to influence yaw instability, and the extent to which directional control of tractor-semitrailers is affected by open-loop stability. The National Hwy. Traffic Safety Administration is requested to advise motor vehicle manufacturers about study findings on vehicle design and use.

SAFETY PERFORMANCE EVALUATION OF SEAT BELT RETRACTORS

Seat belt emergency locking retractor (ELR) performance was measured in a sample of 44 automobile models (1976-1978) sold in Canada which were subjected to 30-mph frontal barrier crash tests. Vehicles ranged from subcompacts to full-size cars. Restraint system performance was correlated with such parameters as seat belt configuration, webbing elongation and compaction on ELR, ELR performance, shoulder belt peak load and loading profile, vehicle acceleration profile, vehicle interior compartment geometry, and injury criteria (including head injury). Although retractors locked at the onset of dummy movement in 30-mph tests, the driver dummy struck the steering wheel and column and the passenger dummy struck the dash. Impact forces were attenuated by restraint systems and did not appear to be life threatening, based on Canadian and U.S. motor vehicle safety and occupant crash protection standards. All ELR's performed satisfactorily, but considerable performance differences were observed with respect to actuation time and webbing extension. The number of interacting variables in each restraint system made a direct determination of the effect of a particular ELR on occupant crash protection very difficult. These test data can be used as an accident investigation tool to understand the mechanism of restrained occupant injuries and to explore the effectiveness of occupant protection safety standards.

IMPROVING SAFETY BELT ACCEPTABILITY TO THE CONSUMER

Specifications and criteria to improve safety belts by eliminating comfort and convenience problems are discussed. Major comfort and convenience problems for automatic safety belts include fit of the shoulder belt across the occupant, shoulder belt pressure exerted against the occupant, latch plate accessibility in front and rear seats, buckles getting lost between seat cushions, webbing retraction, retractors that lock up when being put on or tighten across the occupant's lap while being worn, and retractor systems with excessive shoulder belt slack. Automatic safety belts will be standard equipment in many new cars, beginning with 1982 models. The specifications and criteria to guide auto manufacturers are intended to reduce the likelihood of consumer rejection and nonuse of both automatic and manual safety belt systems. It is important that designed aspects of restraint systems and daily system operation be reliable.

ASSESSMENT OF SEAT BELT USAGE--METHODS/ RESULTS/RECOMMENDATIONS

The effectiveness of seat belts in reducing car crash fatalities and injuries is considered, and increased use is recommended to achieve individual and societal benefits. Dimensions affecting seat belt use are comfort, convenience, effectiveness, and occupant perception of risk. Seat belt use surveys indicate that seat belt systems are inconvenient and uncomfortable to use but that they offer real protection to car occupants. Productive programs for increasing seat belt use can be established on the basis of public attitudes, the imminent installation of passive seat belts in front car seats, and the possible adoption of mandatory seat belt use laws. The impact of automatic seat belts and mandatory seat belt use laws is considered.

THE DEGREE OF BENEFIT OF BELTS IN REDUCING INJURY--AN ATTEMPT TO EXPLAIN STUDY DISCREPANCIES

Seventeen safety belt studies are reviewed to identify possible causes for the disparate assessment of safety belt benefits in accident injury reduction. Published studies report wide variations in the extent to which lap and shoulder belts or lap belts alone reduce injuries and deaths in automobile crashes. In most studies, occupant injury is classified according to one of several categories on a subjective rating scale for lack of an objective measure; other studies define injury according to arbitrary categories with different boundaries. Factors that contribute to the disparity include differences in injury scale values, inaccuracies in reporting occupant belt status, and variations in sampling criteria. Supporting data are appended.

SELECTION BIASES IN THE SAMPLING AND MEASUREMENT OF SAFETY BELT USE

Safety belt use in the Detroit area was studied during 1977 in conjunction with an effort sponsored by domestic auto manufacturers to increase use through mass communication techniques, in this case, by a campaign involving the slogan, "Somebody Needs You." The study methodology incorporated a sophisticated sample design and strictly controlled procedures utilizing 224 observation sites. The possibility of generating sample selection biases when using a few sites that may exclude some driver groups was demonstrated. Biased estimates of change were also shown to be possible, even when using the same few sites in repeated studies. Differences between the Detroit study and a study conducted by the National Hwy. Traffic Safety Administration (NHTSA) are analyzed. Variations in results are attributed to sample selection biases in the NHTSA methodology. Procedures followed in both Detroit and NHTSA studies are described in appendixes.

A COMPARATIVE ANALYSIS OF FACTORS IMPACTING ON SEAT BELT USE

A national survey of 1,500 adults and 500 adolescents identified major factors that explain driver seat belt use. Particular attention was paid to the role of interpersonal interaction and instruction in instigating and reinforcing seat belt use. The significance of interpersonal interaction (peer and authority pressure) was assessed in relation to the impact of demographic variables, perceptions of seat belt comfort and convenience, attitudes toward seat belt use, and establishment of the seat belt "habit." Interviews conducted in 1977 revealed seven factors in driver seat belt use: propensity to use seat belts; interaction in the vehicle between drivers and adult-teenage passengers; general affective attitudes about seat belts; fear of entrapment; perceptions of comfort and inconvenience; passenger-driver interactions; and significant events and conditions. Persons with inertia reel restraint systems in vehicles were most likely to have positive attitudes about seat belts and to feel comfortable wearing them. Seat belt use was proportional to the formal education level of drivers.

A MANUAL FOR DESIGN AND CONSTRUCTION OF BICYCLE PATH PAVEMENTS. FINAL REPORT

A user's manual for the design and construction of Class I bike path pavements is presented. The dramatic increase in the number of bicyclists has resulted in an equally significant increase in the number of bicycle accidents and fatalities. Safety, recreation, and transportation are reasons given for the construction of bicycle paths, although the costs of construction have often been prohibitive. The user's manual is intended to provide engineers and planners with guidelines for the selection of low cost bike path pavement structures under varied service conditions. Guidelines are given for material characterization and construction requirements associated with various pavement structures. Steps in the general design approach to bike path pavement construction include generating design inputs for traffic the pavement is to support, climate of the region, and subgrade soil properties; selecting pavement sections; conducting economic analysis of pavement sections; selecting an optimum pavement system; characterizing material properties; and establishing construction guidelines and specifications for the proposed pavement system. A flow chart illustrates these steps. Information is appended on pavement design, material testing methods, and soil stabilization in bike path construction.

COMMUNITY BROKERAGE OF TRANSPORTATION SERVICES FOR THE ELDERLY IN MOUNTAIN VIEW, CALIFORNIA. FINAL REPORT

A unique way of providing transportation and related services to elderly and handicapped individuals in Mountain View, Calif., is reported. The Mountain View Community Broker Demonstration Project was designed to combine information and referral with a personalized transportation system. A community broker furnished clients individualized primary service information and scheduling assistance. The broker also drove clients to their destinations in a 12-passenger van. Most popular trips were for shopping, a nutrition program, and commercial meals. Ridership never reached expected levels and estimated operating costs of the project were high ($29,285 for 8,776 passenger trips, cost per trip of $3.34, and revenues of $3,432). The community broker concept and project operations are explained. Comments are offered on how a community broker project can be successfully integrated into the social service network for elderly and handicapped individuals. Excerpts from the community broker/driver log and the form used to survey project users and nonusers are appended.

SUBSIDIZED TAXI PROGRAMS FOR ELDERLY AND HANDICAPPED PERSONS IN THE SAN FRANCISCO BAY AREA. FINAL REPORT

Six subsidized taxi systems serving elderly and handicapped people in the San Francisco Bay area were evaluated in order to
identify similarities and differences among programs and to a
certain program cost-effectiveness relative to taxi operators, su
sidizers, and users. Interviews were conducted with clients, an
cost and ridership data were collected. Subsidized taxi servic
appears to be economically viable as a mode of providing tran
portation for elderly and handicapped people. It is less costl
than most demand-responsive bus systems and requires little
no consumer education. Startup and transition problems tend
be minimal. Concerns that subsidized taxi programs will trigg
impossibly high demand levels appear to be unfounded, a
though phased service implementation is an important aspect
the planning process. Subsidized taxi programs have vario
financial arrangements among taxi operators, clients, and subs
dizers of service. Evidence shows that prepayment schemes a
undesirable. There is some indication that clients are reluctant
utilize the group riding option. None of the six programs h
total capability, i.e., none is able to serve elderly and hand
capped people who cannot use taxis. Program documentation
appended.

THE PHYSICIAN'S RESPONSIBILITY FOR EPILEPTIC DRIVERS

State legislation requiring physicians to report names of epile
tic patients to the department of motor vehicles is considere
The accident rate of known epileptic drivers is about twice th
of the general population. Repeated surveys document that pe
sons with epilepsy fail to report their illness due to soci
psychological, and economic pressures. Although the accide
record for epileptic drivers is relatively high, the degree
individual responsibility is a more important determinant
driving performance. Mandatory reporting laws represent a se
ous infringement on rights of individuals to privacy in person
affairs, and data regarding the efficacy of mandatory reporti
laws are conflicting. The Commission for the Control of Epile
sy and Its Consequences suggests an alternative solution bas
on the premise that primary responsibility for reporting re
with afflicted individuals. The commission recommends th
physicians be required to notify all patients subject to lapses
consciousness of their obligation to report themselves to t
department of motor vehicles. The patient should be notified
writing, and notification should be recorded in the patien
record to relieve the physician of any responsibility if an ac
dent occurs.

A SAFETY SEAT WITH INCORPORATED BELTS. STUDY

Development work is described for a prototype energy-absor
ing car seat with seat belts incorporated in the frame. Anthrop
metrical characteristics (relative to the Italian driver popu
tion), seat dimension, and static driver measurement studies a

discussed. Seat design objectives are outlined concerning driving comfort, maximum visibility for the driver, anatomical positioning of the driver's back, and impact protection. The selected seat belt arrangement is described (symmetrical, crossed system corresponding to belts used in stock race cars, acrobatic planes, and parachutes). A major safety feature of the seat is the use of two hydraulic shock absorbers, which protect the occupant from whiplash in frontal impacts. A series of separate studies on each component feature which was required for practical construction of the prototype includes studies on hydraulic system dimensions, sliding of the longitudinal adjustment of the seat back, ideal curves for back shape, and the metal framework of the system and support points for the safety belts. Photographs of the safety seat system are included. The prototype soon will be installed in a production car for driving tests, ending with a frontal impact test.

SAFETY SYSTEMS OPTIMIZATION MODEL

The Safety Systems Optimization Model is an experimental computer program which is designed to make large-scale simulation studies (involving thousands of runs) more practicable. The approach is to substitute simple approximations for the otherwise prohibitively expensive performance of many multi-degree-of-freedom dynamics simulations. The model presently estimates overall performance of some concept for each of 852 conditions of accident exposure. The two classes of simulation involved are those of the vehicle structure, and the restrained occupant. The model can automatically step through incremental variations in certain vehicle and restraint parameters, going through the 852 conditions each time, within user constraints specified for the conceptual vehicle. The model is necessarily several steps removed from reality, but its value is its theoretical estimation of both struck and striking vehicles in many simulated crashes. An example of a model run is provided for a 3000 lb conventional car using arbitrarily chosen cost and materials substitution constraints. Two solutions were obtained, one for three-point belts assuming 70% usage, the other for air bags with 100% lap belt use and 70% three-point use in the "other" cars. Suggestions are provided for future improvement and expansion of the model.

MARKET-RELATED PASSENGER CAR DESIGN TO IMPROVE COLLISION PROTECTION FOR "OWN" VEHICLE AND "OTHER" VEHICLE

A method is described for evaluating and optimizing the "mutual" protection characteristics (compatibility) of vehicles in a frontal collision, with specific reference to the accident situation in a particular market. The method is based on an exact market and accident analysis covering the cumulative frequencies of vehicle masses, of front structure deflection characteristics, and of closing velocities in frontal collisions resulting in personal injury. Using this analysis and a collision model, frontal collisions can be simulated and evaluated for every possible "other" car. Results enable the degree of aggressiveness in a frontal collision to be evaluated of a specific car in a particular market area. The data obtained are used to determine the optimum design of the vehicle front structure and restraint system. The method is applied to the West German market using the dynamic crush in a 30 mph fixed barrier crash as the criterion for the deflection characteristic of the front structure.

DEVELOPMENT AND PERFORMANCE OF PASSIVE RESTRAINT SYSTEMS

Results are presented on the performance of the VWRA (Volkswagen Restraint Automatic) system in 0 degree frontal barrier (Federal Motor Vehicle Safety Standard (FMVSS) 208 requirements), 30 degrees frontal barrier, and lateral (FMVSS and Economic Commission for Europe requirements) crash tests. The VWRA system comprises a torso belt with dual sensitive automatic locking retractor, knee bolster, seat, and seat belt anchorage connected to the seat frame. Results are given in terms of head injury criterion, resultant chest acceleration, and femur force measurements. For frontal impact tests, results are also given for a VWRA system with lap belt added, and a three-point belt system. For the lateral impact tests, three different restraint concepts are compared: driver and rear seat passenger without restraint system; driver restrained with three-point belt, rear seat passenger with lap belt; and driver with VWRA, rear passenger with lap belt. Results are reported of U.S. investigations of accidents involving VWRA-equipped cars. Possible improvements to the VWRA system, such as preloader and belt force limiter, are described. The potential of restraint systems today, both active and passive, with respect to injury reduction, has been demonstrated with the VWRA system.

MATCHING OF CRASH SENSORS TO CRUSH CHARACTERISTICS OF A VEHICLE

Procedures and results are described of various performance tests of air bag G-sensors mounted either on the radiator support or dash panel of a subcompact vehicle. The four test categories included Federal Motor Vehicle Safety Standard 208 barrier crashes, real-world crash types, barrier crashes for sensor actuation threshold performance, and exposure to various shocks expected during normal vehicle service. Test results are compared with results of computer simulations of sensor mass response to crash pulse. A prioritization of sensor performance test modes is presented, as well as four possible sensor schemes. It is concluded that forward- and dash-mounted sensors each have their disadvantages and advantages in terms of sensing time, crash discrimination capability, and agreement with simulation results. Their combined use is preferable. It is concluded that a sensor actuation threshold to meet a narrow speed range will be difficult to achieve because of variations in body crush characteristics. Vehicle front modifications are necessary in order to improve sensor/vehicle interface for various crash types.

IMPROVED TEST PROCEDURES FOR FRONTAL IMPACT

Results are presented of tests carried out in support of the development of new impact test procedures for European legislation on improved car frontal crash protection. One series of tests involved full-scale crashes with seat-belted dummies to compare car-to-car frontal impacts with various car-to-barrier tests. The angled, wood-faced barrier test was determined to be the most suitable. A second part of the test program involved car-to-barrier impacts using 12 models of current production cars (European and Japanese makes): perpendicular at 54 to 59 kph; partial barrier, 30% offset, 49 to 50 kph; and 30 degree angled, wood-faced barrier, 58 to 60 kph. Based on results of this testing, it is suggested that the 30 degree wood barrier test at a speed range of 55 to 60 kph replace the 48 kph full frontal impact now used in European legislation. An interior test using a free-flight spherical headform is proposed, and results reported from 22 interior impact tests on each of the 12 models used in the barrier tests. Consideration is given to the problem of choosing the impact speed and the pass levels for dummy loads for a legislative test, as well as the variability in loads and accelerations measured on dummies in full-scale tests.

RESULTS OF COMPARATIVE FRONTAL CRASH TESTS

Results are presented from two crash test programs designed to gather comparative data on occupant behavior and injury criteria, and concerning vehicle velocity change, deceleration characteristics, and deformations, for different crash modes. The first phase consisted of 71 tests, either car-to-barrier (centered, offset, or at an angle) or car-to-car crashes with various overlaps. Various dummy types were used. A great disparity in results was found, both between crash modes, and between different cars for the same crash mode. It was concluded that the 30 degree barrier test was most representative. The second phase consisted of 52 tests comparing only the 0 degree and 30 degree barrier tests, using the Part 572 dummy. The scatter in results using this dummy was found to be less than that obtained using first-generation dummies in the first test series. In comparison with the 0 degree barrier test, the 30 degree barrier test was found to give a slightly lower velocity change, a lower maximum deceleration, and a much greater deformation to the car; and, with respect to the dummy, a lower Head Injury Criterion with small data disparity, chest deceleration at the same level with a slightly lower severity index, and femur loads at the same level.

UPGRADED FRONTAL CRASH PROTECTION FOR MOTOR VEHICLE OCCUPANTS

The National Hwy. Traffic Safety Administration (NHTSA) has promulgated a revised Federal Motor Vehicle Safety Standard (FMVSS) 208 (Occupant Crash Protection) which requires, by model year 1984, that all new passenger cars sold in the U.S. be equipped with automatic protection systems (air bags or passive seat belts). FMVSS 208 emphasizes frontal protection, since about 50% of automobile occupant fatalities occur in this crash mode. The standard requires protection up to a 30 mph rigid barrier impact, but accident analysis indicates that higher speed protection is necessary. Although FMVSS 208 offers some level of protection above 30 mph, improved vehicle structures and restraints are necessary for further fatality and injury reductions. In order to accomplish this improvement in frontal crash protection, as well as in other crash modes, NHTSA has developed the 400 Series rulemaking activity. Prime consideration will be given to specifying vehicle compatibility requirements (i.e. tradeoffs between vehicle aggressivity and crashworthiness covering a wide range of vehicle types and weights, and accident modes, as well as vehicle front-end aggressivity to pedestrians). The 400 Series will incorporate the development of advanced test dummies and injury criteria, as well as improved laboratory test procedures. The final product will be a family of vehicles which will demonstrate enhanced safety in all crash modes (frontal, side, rear, and rollover). The anticipated effective date of the 400 Series is Sep 1988.

A CONCEPT OF INCREASING COMPATIBILITY OF PASSENGER CARS

An ongoing research project of HUK Verband (Assoc. of German Automobile Insurers); Inst. of Automotive Engineering, Technical Univ. of Berlin (TUB); and Volkswagenwerk A.G.

(VW) is reported the goal of which is to determine means of improving passenger car compatibility. The project involved analysis of data on car-to-car crashes (involving casualties) in the Federal Republic of Germany in order to rank collision types according to their significance. Five selected collision types were studied in actual vehicle crash testing and by computer simulation. VW Rabbits and Audi 100's were studied, and Federal Motor Vehicle Safety Standard 208 injury criteria used. Dummy loadings obtained in experiments and by simulation were compared, and functions derived for relating dummy loading to accident criteria. Computer optimization of deformation structures has indicated possible vehicle and restraint system design changes for improved automobile compatibility and analyzed the effectiveness of the technological changes. Among other things remaining to be accomplished are cost-benefit analyses of proposed design changes.

A STUDY OF THE BODY STRENGTH ON SEAT BELT SYSTEMS

The deformation behavior of seat belt assembly anchorages under static and dynamic load conditions has been experimentally studied to determine the relationship between seat belt safety requirements (specifically, Federal Motor Vehicle Safety Standard (FMVSS), Seat Belt Assembly Anchorages) and the design of vehicle body structures. The experiments showed that although the standard load of FMVSS 210 (static test) is approximately equivalent to the input from a 50th percentile dummy in an actual 30 mph head-on collision, the anchorage deformation with FMVSS 210 load was significantly greater than that experienced in the 30 mph crash. Static load conditions were examined for the simulation of an actual 30 mph head-on collision. The load in a static test which causes the same amount of deformation as in an actual collision was determined to be from 52% to 86% of the load in the collision. The appropriateness of the static seat belt anchorage strength of FMVSS 210 and other standards is therefore questioned. As a more realistic approach, a selection system is proposed in which the seat belt anchorage strength will be acceptable if it passes any one of the following tests: static test with revised load, FMVSS 208 conditions, or bench collision simulation test. It is felt that this approach will permit the construction of lighter weight vehicles (for improved fuel economy), and the design of seat belts which are easier to use.

THE INFLATABLE DIAGONAL BELT (IMPROVEMENT OF PROTECTION IN THE CASE OF FRONTAL IMPACT)

A series of dynamic tests to initially study the effectiveness of an inflatable diagonal belt relative to other restraint systems such as the three-point belt was carried out with a live subject (a baboon). The inflatable diagonal belt in the pre-inflated state gave more protection to the animal than a three-point system at an impact speed of 48 kph, and no injuries were observed in the animals restrained by the preinflated diagonal belt at 60 kph (three-point belt not tested at this speed). From the findings of the animal experiments, an inflatable diagonal belt system was designed. Adjustment tests were made on the gas generators, and the belt fabric was selected for compatibility with the gases. Testing of the restraint system carried out at 50 kph with the Hybrid II dummy showed that this dummy was not suitable for the assessment of the inflatable diagonal belt. The advantages of this system at the present stage of study have been mainly demonstrated in the tests with the live subjects. Relative to other inflatable restraint systems, it offers two great advantages: ensures protection even if it fails to inflate; and in the case of inadvertent firing, produces no loss in visibility for the driver, no excess pressure effect in the passenger compartment, and a very low sound level.

OCCUPANT PROTECTION IN FRONTAL IMPACTS

The design of passenger cars for occupant protection in frontal crashes is outlined. After determining representative vehicle speeds for engineering analysis, the statistical distribution of injuries among car passenger for the different parts of the body is examined, using injury criteria (Federal Motor Vehicle Safety Standard 208). In the present case, the chest injury criterion is considered sufficient for development purposes. The longitudinal component of the resultant chest acceleration is chosen for study because it corresponds with the restraint system and is compatible with vehicle acceleration. Based on sufficient test evidence, the car's longitudinal acceleration is selected as the vehicle design parameter. Starting with the test results of an experimental car, the first indication of the front-end collapse behavior is provided by the acceleration characteristic of the vehicle. The energy-absorbing capabilities of the individual front-end components are analyzed in crush testing. All individual component results are used as input into a computerized simulation model. The first simulation establishes compatibility with real crash test results. Extensive analysis follows for ordering of priority areas. Order-sensible modifications are computed and checked vs. total system effect. This process enables an iterative design optimization with regard to vehicle acceleration. Optimization results are converted into the design and verified by further crush testing before a confirmatory vehicle barrier test is performed. A flow of the developmental process is appended.

DESIGN OF STEERING COLUMNS FOR PASSIVE RESTRAINT APPLICATION

The functions and characteristics of two different types of steering column assemblies appropriate for application in the driver air cushion restraint system (ACRS) and the passive belt system are described. The air cushion and passive belt columns are critical components which determine the effectiveness of each system. The functions and characteristics of each type of column are unique. An air cushion column performs two vital functions: it orients restraint loads and absorbs driver kinetic energy. To do this, the ACRS column axis should be oriented as closely as is practical to the torso center of gravity of the 50th percentile male driver. The height and angle of this column should be selected to achieve either a pitching or a controlled submarine trajectory. The characteristics of the energy-absorbing unit of the ACRS column are a function of the column orientation, design crash severity, and the vehicle deceleration waveform. An ACRS column should be stable relative to its energy-absorbing function so that the collapse force of the column is sufficiently insensitive to nonaxial loads. The passive belt column performs a dual role: it must be a positive protective device when the belt is circumvented, and it must be a noninterfering element of the vehicle interior when the belt is worn. Assessing the net benefit of conventional energy-absorbing columns on the basis of field data is beyond the present level of data sophistication. A satisfactory approach in designing a passive belt column is to design the column to function in a dual mode: to perform as a function of the driver's trajectory which, in turn, can be made sensitive to whether or not the belt is circumvented. Such a column configuration is comprised of a well-padded wheel which has a yielding rim, a self-aligning element, an axial collapse unit, and yielding support bracketry.

JOINT BIOMECHANICAL RESEARCH PROJECT (KOOPERATIONSVERBUND BIOMECHANIK). PRELIMINARY REPORT

Some initial results are reported from the Joint Biomechanical Res. Proj., Kooperationsverbund Biomechanik (KOB), a large-scale program of reconstructing real accidents (each accident case involving five to six reconstructions using dummies and three using human cadavers). Some reconstructions of head-on, lateral, and pedestrian collisions are reported to illustrate the methodology used, to show its feasibility, and to indicate the results which can be expected. The areas of scatter for the preliminary results are discussed. The general goals of the research project are to obtain information on the human body'
tolerance limits under realistic impact conditions, and to deter
mine a significant correlation between real injuries and dumm
test results, as well as between human tolerance levels an
injury protection criteria. When the program is complete, it
hoped that sufficient information will be available to establis
appropriate performance standards for Europe.

SYNTHESIS OF HUMAN TOLERANCES OBTAINEI FROM LATERAL IMPACT SIMULATIONS

Results are summarized from biomechanical experiments usin
fresh, unembalmed cadavers to study human tolerances to sid
impacts. The findings are the most recent from free-fall tes
performed over the past few years. In studies of head impac
no relationship was found between Head Injury Criterion (HIC
and Abbreviated Injury Scale values. For these lateral sku
impacts, only a slight likelihood of serious injury was found. N
constant relationship was found between the accelerations mea
ured on a dummy and those on a cadaver in these head impact
No positive conclusions can be drawn concerning the protectic
provided in car-to-car side collisions unless the dummy's beha
ior yields a head impact velocity close to that of the huma
head, which does not occur when the shoulder acts as a brac
and when the chest deflects insufficiently. HIC 1500 can
determined in impacts using a separate head rather than th
complete dummy. For chest side impact experiments, the inj
ries found were essentially rib fractures. The number of fra
tures can be an injury level indicator. Correlations were mac
between the number of fractures and the force applied to th
chest, and also the relative deflection of the chest and th
thoracic acceleration. Chest protection criteria can be esta
lished when an appropriate anthropo-dynamic dummy has bee
developed and tested. On the basis of pelvis impact experimen
and other studies, 80 to 90 g/3msec to the pelvis seem to be
conservative level of human tolerance. For a Part 572 dumm
protection criterion, a level of 90-100 g/3msec could be consi
ered. For the experimental condition of the side wall stoppir
the thorax without head impact, it is concluded that there is
need for a neck protection criterion.

PREDICTION OF THORACIC INJURIES AS A FUNCTION OF OCCUPANT KINEMATICS

Injury-predictive models of the severity of blunt thoracic trauma have been developed using the data gathered in a series of impact tests utilizing 18 cadaver subjects. Two classes of tests were conducted to generate various levels of injury: tests on an impact sled where the subjects interacted with padded or rigid side door structures in side impact; and controlled energy impacts delivered to the side of the thorax using a flat-faced pendulum impactor. The instrumentation which was designed to monitor kinematics consisted of a matrix of accelerometers surgically placed on the bony exterior structure of the thorax. The active axes of the accelerometers were chosen to represent the three orthogonal axes, and hence, to provide information on direction of impact. After the tests, autopsies were performed to obtain a level of injury reported as an Abbreviated Injury Scale (AIS) number. The injury-predictive models have the AIS number, the number of rib fractures, or derivatives thereof, as the dependent variable and various features of the time-dependent acceleration traces as the independent variables. The features which show the greatest correlation with the level of injury, and hence, which hold the greatest potential for building injury-predictive models have been found to be quantities related to velocities or integrals of acceleration pulses. After quantities such as these were derived from the accelerometer traces, those with the highest correlation to injury measures were selected as candidate independent variables. The predictive models, were then generated using regression software.

PROTECTION CRITERIA FOR OCCUPANTS AND PEDESTRIANS

The method of equivalent accident characteristics (EAC) is described as a means of correlating dummy load (DL) values obtained in computer simulations with injury severities (Abbreviated Injury Scale values) determined by in-depth investigations of real accidents. DL's of certain body parts are separately investigated and described as a function of all main parameters which make up accident characteristics (AC), by computer simulation. The AC's comprise such parameters as velocity, mass, stiffness, design characteristic, deformation, and intrusion. The EAC is a measure of accident severity by the extent of injuries to a body part, and shows the influence of the different AC's. Two examples are presented for determining the EAC (side impact, occupant on the struck side; and frontal impact, belted driver and belted occupant).

CONSIDERATIONS IN SIDE IMPACT DUMMY DEVELOPMENT

Side impact crashes produce a significant portion of total fatalities and injuries in U.S. traffic accidents, and accident data indicate that the injury susceptibility of occupants in these crashes increases with the level of crash intensity and occupant age. The National Hwy. Traffic Safety Administration has initiated a program to upgrade the requirements of Federal Motor Vehicle Safety Standard 214, Side Door Strength, by replacing the current static loading test with a dynamic test. An impacting device will be used to simulate a striking vehicle and an anthropomorphic test dummy to assess the human injury hazard within the struck vehicle. A method of assessment which determines the most appropriate test conditions and levels of protection for those conditions is also necessary before promulgation of the new rule. Attenuation of the intensity of the crash environment appears to be the most feasible way to reduce injuries and fatalities. By initially using the level of crash intensity as the measure of desired performance and subsequently transferring that desired performance to an equivalent set of measurements on an anthropomorphic dummy allows utilization of a dummy system that is representative of any portion of the population at risk.

DEVELOPMENT OF THE NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION) ADVANCED DUMMY FOR THE OCCUPANT PROTECTION STANDARD UPGRADE

The National Hwy. Traffic Safety Administration's (NHTSA) proposed development plan for an advanced test dummy to serve the long-range U.S. Vehicle Occupant Crash Protection upgrade needs is discussed. Although the current regulation dummy can be used for evaluating occupant injury countermeasures, a dummy is required which can more realistically simulate global human response. The five major areas of the development program are discussed: review of field accident data, biomechanics research, dummy design characteristics, definition of the dummy and the scope of its application, and legal considerations. NHTSA, through Docket 79-05, is actively soliciting from the international community proposals and research data for incorporation into its program. A list is presented of 20 items for initial discussion requiring input by interested parties to initiate the program. The major milestones in the program call for an advanced notice of proposed rulemaking (ANPRM) by early 1980, an NPRM in the fall of 1983, and the issuance of the rule by early 1985.

PRESENTATION OF A FRONTAL IMPACT AND SIDE IMPACT DUMMY, DEFINED FROM HUMAN DATA AND REALIZED FROM A "PART 572" BASIS

Research is described for improving the human response characteristics of the Part 572 dummy in side and frontal impacts. Biomechanical data were obtained in free-fall, side impact experiments using human cadavers in order to determine the force/deflection characteristics of the human chest. Using the experimental data, the Part 572 dummy's thorax was redesigned for improved response during side impact conditions. Modifications were made to the Part 572's shoulder assembly to give it the range of motions observed for cadavers in vehicle crashes. Modifications were also made to the Part 572 arm, in order to improve its deformation characteristics. Results of dynamic testing of the redesigned dummy are described: frontal impact tests were compared with those of the Part 572 dummy, and side impact tests with those of the human cadavers. Frontal impact tests using Part 572 dummies and cadavers, both restrained by three-point belts, indicated dissimilarities in their submarining behavior. Differences between the Part 572 and human being pelvic areas, and some modifications to the dummy pelvis to align its submarining behavior to human response are described.

EXPERIMENTAL APPLICATION OF ADVANCED THORACIC INSTRUMENTATION TECHNIQUES TO ANTHROPOMORPHIC TEST DEVICES

A 12 accelerometer instrumentation array developed for use in cadaver experiments on thoracic injury has been adapted for ATD (anthropomorphic test device) installation. Accelerometers around the periphery of the Part 572 chest register different acceleration signatures for different directions, levels, and time durations of impact. A series of modifications has been made to the ATD to improve the side impact response of the thoracic regions. These modifications ranged from slight changes in structure to radical altering of the thoracic lateral dynamic stiffness, mass distribution, and rib linkages. When a series of side impact tests was conducted using the modified ATD's, their response was similar to the mean cadaver-based response. The modified thoracic structures are prototype designs which are intended for lateral impact use only. The use of injury-predictive models to predict thoracic injury levels using kinematic data from the modified ATD test indicates that this is a promising approach to injury assessment.

A NEW DESIGN FOR A SURROGATE SPINE

A surrogate spine suitable for installation in a 50th percentile anthropomorphic test device (Part 572 ATD) was designed, fabricated, and tested. The design was based on the synthesis of a planar linkage joining two rigid bodies. Its length and the location of pin joints were determined by means of an optimization program which minimized the error of the relative motion between the pelvis and the first thoracic vertebra in the least squares sense. The design was based on experimental data obtained from cadaveric impact experiments. The physical model of this spine link is 464 mm long and was made to fit within the spinal box section of a Part 572 ATD. The upper pivot is superior to the box section and the lower pivot is in the pelvic area. The rubber spine and the weights within the box section were removed. The rib cage could swing approximately 13 degrees about the upper (T1) pivot. Sled impact runs were conducted with the surrogate spine and its dynamic response compared favorably with that obtained from living human and cadaveric tests, although it is noted that T1 Kinematics of the Part 572 dummy are not comparable to human data.

REALISTIC TEST CONDITIONS FOR EVALUATION OF PASSENGER CAR OCCUPANT PROTECTION

The concept of compatibility is applied to the determination of realistic barrier impact test conditions for evaluating the occupant protection of passenger cars. Compatibility involves the design of a vehicle front structure to ensure protection of that vehicle's occupants in the event of a head-on collision, either single or vehicle-to-vehicle, as well as the protection of the occupants of other vehicles which are hit in the side by that vehicle. For type approval (compliance with government regulations), a new vehicle undergoes crash testing. The primary test is the impact into a rigid barrier at the same predetermined speed, for all vehicles. This test condition makes no allowances for the varying risk of injury which occurs in road accidents involving vehicles of different weights. With the aid of the compatibility concept, a correlation is made between the barrier impact speed and the overall risk existing in actual road traffic from the mass of the vehicles involved. For heavier vehicles, the test impact speeds should be lower; for lighter vehicles, they should be higher.

IMPROVED TEST PROCEDURES FOR SIDE IMPACT

The development of new impact test procedures for European legislation on improved car side impact protection is described. A full-scale side impact of a mobile barrier with the side of a car is a desirable test of the protection provided for car occupants. The loadings on the head, torso and pelvis of a specialized dummy are essential parameters of such a test; dummy acceleration levels are not sufficient as they fail to detect crushing injuries. The impact may conveniently be perpendicular into a stationary car under test and representative of a vehicle striking at 50 kph between the A posts and rear wheel arch. A small rigid faced barrier 1m wide, 600 mm high and 200 mm above ground with edge radii of 75 mm striking the car under test at 35 km/h is a good representation of this situation. Results show the need for strengthening the side structures of some cars, particularly to maintain tensile strength from A post to the rear through the door hinges and latches. A high tensile strength for the B post and its ends is particularly important. At the same time the need for the components on the inner faces of doors to be sufficiently soft to dummy impact is also demonstrated and energy-absorbing padding may usually be needed. Some current car designs come close to passing the suggested test. Auxiliary tests of the padding or suitable design of the side components that might possibly be struck by the head are also necessary. It would be desirable to improve compatibility between car fronts and car sides of different designs. Testing with a rigid faced mobile barrier is a means of checking this, if load cells are fitted to the barrier face. It appears that a suitable procedure for compatibility testing would be: to impact the stationary car head on using a 2 m wide 1100 kg mobile barrier at 40 km/h, recording barrier deceleration and load cell forces, and to impact the same car at 90 degrees into the driver's R point, using a 1 meter wide 1100 kg mobile barrier at 35 km/h, recording barrier deceleration. Whether the face of the barrier be rigid or deformable, its shape, positioning and design are critical factors for the designs of cars that would have to meet the regulatory side impact test.

SIDE COLLISION

The most significant variables in side collisions are discussed and illustrated with experimental results: contact zone, collision direction, velocity, and models of cars involved. A test with both cars in motion is compared to one involving a moving car and a stationary car. Tests using rigid vs. deformable, moving barriers are also compared. The deformable, moving barrier used by Fiat in its crash testing program is described (variable weight, front face honeycomb modules). Some results using this barrier show good agreement with car-to-car test results. The use of Fiat's dynamometric barrier in crash testing and mathematical models provides a methodology for evaluating occupant and vehicle behavior for different car models. This approach greatly reduces the number of cars which actually have to be crash tested and provides more information. Six tests are sufficient to provide evaluation data on both cars (occupants included) for 15 different collision types.

LATERAL COLLISION TESTS

The results of a large-scale program to investigate lateral crash test procedures are tabulated. The program was designed to evaluate whether the proposed ECE (Economic Commission for Europe) test procedure WP 29-463, Rev. 1 (35 km/h rigid mobile barrier test) is appropriate and realistic for side collision simulation, and to establish a fundamental data base for the development of a possible test procedure and performance criteria for lateral collision simulation. Car-to-car crash tests using same model cars, ECE barrier-to-car tests, and car-to-car crash tests using different model cars were conducted. Results show that the ECE barrier test and car-to-car tests are not comparable in terms of impacted car deformation, and dummy behavior. Although a complete test procedure cannot be specified at this time, it is suggested that the struck car be stationary, and that the impact angle be 90 degrees with the center line of impact aligned with the front occupant of the struck car. A mobile, deformable barrier is being developed to provide a more realistic simulation of lateral impacts. A dummy suitable for side impact tests must also be developed.

STATUS OF THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION'S RESEARCH AND RULEMAKING ACTIVITIES FOR UPGRADING SIDE IMPACT PROTECTION

In the National Hwy. Traffic Safety Administration's 1977 rulemaking plan, improvement in side impact protection was formally established as a top priority. This plan calls for a Notice of Proposed Rulemaking (NPRM) on an upgrade of Federal Motor Vehicle Safety Standard 214 in 1980. Research projects are underway to generate data on how occupant compartment integrity can be improved and how occupant injuries can be reduced by changes to the side structure and by modification of the interior of the vehicle. The upgrade program contains four major areas of activity: development of a test procedure, including the development of a moving barrier impactor; development of a dummy and associated performance criteria; development of vehicles that can be used to demonstrate performance; and analysis of accident data to support the other three activities. Progress to date in these areas is reported; and cost, weight, and leadtime studies are briefly discussed. A schedule of the total program is provided, with anticipated dates for dummy, barrier impactor, and rule NPRM's.

OCCUPANT PROTECTION IN LATERAL COLLISIONS: SPECIAL FEATURES OF RENAULT E.P.U.R.E. (ETUDE DE LA PROTECTION DES USAGERS DE LA ROUTE ET DE L'ENVIRONMENT) (EXPERIMENTAL SAFETY VEHICLE)

Accident and biomechanical data presently available on lateral collisions are reviewed. Results are summarized from initial lateral impacting of the Renault E.P.U.R.E. (experimental safety vehicle (ESV)) in car-to-car tests. Measures to increase the level of protection offered by the ESV in the preliminary collision tests include decreasing inner structure velocity and improving occupant/structure contact. An estimation is given of the increase to the vehicle mass to improve lateral impact protection. Structural reinforcement of the vehicle to decrease inner structure velocity, and padding of the inner structure to improve occupant/structure contact are described. To highlight the progress resulting from these modifications to the E.P.U.R.E., results of a lateral collision test between a Renault 14 and the ESV are compared with those of a collision between a Renault 14 and a Renault 5 conducted under identical conditions. While the reproducibility of the collision test results has not been verified, it is noted that the E.P.U.R.E. level of side impact protection performance has been achieved at the cost of a reduced width at the vehicle window-sill, difficulty in actuating seat controls, and increased weight. The Part 572 dummy is considered unreliable in testing lateral impact.

IMPROVEMENT IN THE PROTECTION AGAINST SIDE IMPACT

The selection of obstacle and impact point, and approach speed for the conduct of side impact tests is described (the most typical side impact being the car-to-car impact at 50 kph, 75 degrees or 90 degrees). Studies of the behavior of occupants in a side impact have indicated that change in speed of the struck vehicle, and intrusion into the passenger compartment are less important parameters in terms of accident severity than previously believed. Instead, the seriousness of the side impact is controlled by two simple physical parameters: the impact spee between passenger and inner wall of the vehicle, and rigidit and energy-absorption characteristics of the area hit by th occupant. A method is presented for calculating passenger t wall impact speed, based upon measurements on the acciden vehicles. Features are described of the Peugeot VSL safet vehicle (derived from the Peugeot 104) for improved safety i side impact.

THE V-SHAPED VEHICLE FRONT--ITS INFLUENCE ON INJURY SEVERITY IN PEDESTRIAN ACCIDENTS AND SIDE COLLISIONS

Results are presented of car-to-pedestrian impact tests usin child and adult dummies and a large V-shaped Prosche 928. O the basis of a literature analysis and the tests performed, it i concluded that a vehicle concept with optimized pedestria protection must meet the following requirements: V-shape front structure, distance from the ground to the lower windshield frame edge of at least 2 m; an energy-absorbing integrate bumper (soft nose); energy-absorbing construction of hood an fenders; and large "effective front area" with minimum stiffening of possible impact zones. Results of car-to-car side impac tests using three models of Porsche V-shaped cars are compare with published test data on pontoon-shaped vehicles. The side impact protection behavior of the V-shaped front car is comparable to that of common European cars. By design changes, th lateral structure could be strengthened. The increased vehicl width of the V-shaped front car is advantageous in side impact but increases the frontal area to its detriment; this width i compensated by a reduced vehicle height. It is concluded tha the V-shaped concept offers a means of reducing passenger ca accident casualties by 10%. It also has an improved air dra coefficient for increased fuel economy.

A STUDY OF VARIOUS SIDE-IMPACT CONFIGURATIONS.

Data concerning side impact crashes investigated during 1977 i the National Crash Severity Study program were examined i four different categories: car-to-car, truck-to-car, fixed object-to car, and rollover. Fatal crash data for the same period obtaine from the Fatal Accident Reporting System allowed a compar son of the relative lethality of the different crash configuration Approximately three out of five fatalities resulting from sid impact crashes were found to occur when passenger cars ar struck by a truck or fixed object. The remaining fatalities occu in side impacts between cars and in rollovers. A series of fiv different real-world side impact crashes is described (includin photographs) to illustrate the potential disparity in size and mass between some vehicles and objects in side impact crashes. The crashes illustrate that side-door beams can play a relatively insignificant role in reducing intrusion and mitigating injury in such crashes. While side door strength is important, other factors, such as occupant-interior impact, interior deformation, exterior crush resistance, and crush resistance of the striking vehicle affect occupant safety. Additional approaches to side impact protection are needed.

THE NATIONAL CRASH SEVERITY STUDY AND ITS RELATIONSHIPS TO ESV (EXPERIMENTAL SAFETY VEHICLE) DESIGN CRITERIA

The National Crash Severity Study (NCSS) is a major accident data collection program whose primary objective is to provide a data base from which statistical relationships between crash conditions and occupant injuries in towaway automobile accidents can be determined and from which the distributions of crash conditions can be estimated. NCSS field data collection operations (Jan 1977-Mar 1979) are described. Statistical data from the current NCSS file (some data missing) are discussed concerning the relationships between occupant injury, and crash mode, crash velocity, and occupant ejection. Efforts in progress address three key issues concerning NCSS data (quality, completeness, and representativeness). Uses of NCSS data in rulemaking by the National Hwy. Traffic Safety Administration are mentioned, as well as in the development of the successor to NCSS, the National Accident Sampling System.

ACCIDENT INVESTIGATION TECHNIQUES FOR SECONDARY SAFETY

Recent progress is described in the U.K. towards developing a multilevel system of accident investigation specifically related to vehicle secondary safety. The application of the national police statistics to determine priorities, the extension of local in-depth investigations for furthering the understanding of injury mechanism, and proposals for an intermediate level system for monitoring changes in vehicle safety features on a sample basis are outlined. The coordination of activities among three teams involved in studying injury causation and alleviation (at the Transport and Road Res. Lab., Birmingham Accident Res. Unit, and Oxford Road Accident Group) is an important part of the work. A procedure is being developed for harmonizing accident investigation techniques (for the study of biomechanics of injury for car occupants in particular) while enabling the teams to retain their own specific objectives and local interests. The current three-year program (1978-1981) of research studies is summarized.

DATA BASE FOR ACCIDENT AND SAFETY RESEARCH ON THE SECTOR OF AUTOMOTIVE ENGINEERING: GENERAL ASPECTS OF DATA REQUIREMENTS AND SUPPLY

From the viewpoint of the Federal Republic of Germany, data requirements for an effective national traffic safety program are discussed. Available data sources are considered: police, insurance companies, hospitals and health insurance companies, the automobile and car repair industries, research organizations, emergency medical services, and consultants. Inclusion of available data in the national traffic safety statistics is seen as problematic, particularly with respect to data interrelationships and representativeness. The solicitation of opinions (by the Federal Hwy. Res. Inst.) from experts in the field of traffic safety regarding data needs is described. Criteria for selecting the type of data to be included in a national traffic safety data base are listed (based on opinions from the traffic safety experts, and on legislative needs). The question of formulating an optimum strategy of data acquisition, access, and updating is presented. Aspects such as completeness of data, linking data files, standardization of data documentation, training in data collection, and coordination of data collection efforts are addressed.

ANALYSIS OF PEDESTRIAN ACCIDENTS TAKEN FROM A ROAD TRAFFIC ACCIDENT INVESTIGATION

Japanese traffic accident fatality and injury trends are discussed for the 1968-1977 period. These indicate that 33% to 37% of the total number of accident fatalities annually are among pedestrians, pedestrian accidents accounting for 22% to 25% of the total accident number. An in-depth investigation of 46 pedestrian accidents which occurred in Japan in 1977 is reported. Of these accidents, 18 were the result of a driver violation, 5 were the result of a pedestrian violation, and 23 were caused by the actions of both road users. The pedestrian error for all cases was running out into the road suddenly (in agreement with the cause of most pedestrian accidents in Japan in 1977). The 46 accidents resulted in nine deaths, 20 severe injuries, and 17 minor injuries among the pedestrians; 33 of the pedestrians were injured or killed when struck by the vehicle front. The front panel and the hood showed the highest potential for severe injury (Japanese Abbreviated Injury Scale). The highest number of accidents involved children. National statistics for 1977 show the highest number of pedestrian fatalities among children under six years of age. In most of the investigated cases, the vehicle impact speed was directly proportional to injury severity.

COLLISION CHARACTERISTICS AND INJURIES TO PEDESTRIANS IN REAL ACCIDENTS

Results are presented of an in-depth analysis of some 3000 injury-producing pedestrian accidents which occurred (1975-1976) in the Federal Republic of Germany. In over 50% of the cases, the pedestrian contacted the outer third of the car front end. Head and leg injuries were the predominant injuries. Elderly adults sustained more fractures of the lower limbs, pelvis, and upper thigh areas. Children had a high incidence of head, torso, and upper thigh injuries as a result of their relative height. Twenty percent of the injured pedestrians were between six and nine years of age, a factor which should be taken into consideration in the design of the car front end. There was some advantage for the V-shape over the pontoon shape for vehicle front ends in terms of overall injury severity. However, differences were found among vehicle shapes with regard to injury of individual body areas. Lower limb injuries were overrepresented with the V-shape; pontoon shape cars had a higher incidence of abdominal and upper thigh injuries. Serious/fatal head injuries were equally distributed. Risk zones for the V-shape are lateral and upper windshield frame, windshield, and bumper/front end area. For the pontoon shape, these zones are rear and front parts of the hood, and lower section of the windshield frame.

A STUDY OF DRIVER CONTROL BEHAVIOR BASED ON ACCIDENT INVESTIGATIONS.

An analysis was made of 11 traffic accidents which were associated with an inappropriate steering action of the driver. Some essential details are given on the driver, vehicle, road and weather conditions, and course of accident. The accidents were grouped into four categories: turning, lane change, avoiding an oncoming vehicle, and inattentive driving. In all groups, it was found that the accidents are attributable to the fact that the drivers' subjective judgment of safety was more optimistic than the objective one. The drivers' errors can be broadly grouped as wrong prediction of vehicle response to steering action, and misjudgment of safety margin. Closed-loop tests (turning, lane changing) were conducted on a test track to investigate the quantification of driver subjective judgment of safety. The results are favorable and indicate the potential of the quantification of subjective judgment for accident prediction using driver-vehicle-environment system models.

COMPATIBILITY OF MASSES AND STRUCTURES IN CAR-TO-CAR LATERAL COLLISIONS

The compatibility of vehicle structures and masses in relatio
ship to accident severity for car-to-car lateral collisions w
investigated through in-depth and survey studies of such ac
dents in France. The severity of car-to-car lateral collisio
increases as the mass ratio increases in favor of the impacti
car. This difference of severity is not related to the fact that
impact speed is greater in heavier cars. The risk for occupa
in cars impacted by heavier cars is closely correlated with
poor compatibility of the relative heights of the bumpers a
rocker panels. This increases intrusion and also raises the occ
pant/wall contact speed above the level attained when only
mass ratios and the relative rigidity of parts dissipating
energy of the impact are considered. The protection afford
would be considerably increased by making the lower parts
the side of the vehicle, just above the rocker panel, more ri
in lighter cars. The geometry of the intrusion of the late
walls, in car-to-car collisions, is such in today's cars that
occupant/wall contact speeds decrease from the pelvic le
upwards to the thoracic level. Consequently, there is less risk
head lesion than in lateral impacts against fixed obstacles. Age
known cause of the variation of the severity of thoracic lesio
did not play a significant role in pelvic or abdominal lesions
the accidents surveyed.

CAR DESIGN FOR PEDESTRIAN INJURY MINIMIZATION

Data from an in-depth, at-the-scene study of pedestrian ac
dents have been used in conjunction with data from a stu
using existing police and hospital records to examine the inf
ence of exterior car design, impact speed, and pedestrian age
pedestrian injuries. For pedestrians struck solely by the fronts
cars or delivery trucks, head and leg injuries were found to
the most frequent injuries. The incidence of injury to any part
ular body area increases with overall injury severity. For the
with only minor injuries, leg injuries are more frequent th
head injuries except for the very young child. For those w
non-minor, non-life-threatening injuries, and for those with li
threatening injuries, head injuries were the most frequent. Co
tact with the vehicle is shown to be the main cause of n
minor injuries, and that their severity is dependent on imp
speed, whereas the severity of ground contact injuries is n
Age influences pedestrian injuries in two ways: height a
weight relationship to contact area, and injury tolerance (elde
are more susceptible to injury). The primary vehicle conta

are responsible for virtually all non-minor pelvic and leg injuries, the main sources of injury being the bumper and front edge of hood. Secondary contacts result mainly in head injuries, the main source being the windshied frame, next the hood. The introduction of compliant "pro-pedestrian" front structures designed to reduce pelvic/leg injuries will likely reduce "Wrap Around Distance" to the head contact, resulting in fewer windshield contacts but more with the hood. The hood could be designed in terms of head contact (e.g. elimination of localized stiff areas). Testing of the dynamic stiffness of the vehicle front structure is the most important aspect of pro-pedestrian vehicle structure evaluation.

A SYNTHESIS OF AVAILABLE DATA FOR IMPROVEMENT OF PEDESTRIAN PROTECTION

An investigation of pedestrian accidents in France indicated that the most serious pedestrian injuries were those to the head and were the result of contact with the vehicle. Two series of experimental studies of head-to-vehicle impacts are described: vehicle crashes using adult and child dummies, and cadavers; and free-fall impacts of dummy heads onto the front part of a car. The development of a mathematical model of the pedestrian-vehicle collision is discussed, which was validated by experimental collisions. Design features (related to A-pillars, windshield, and hood) are described for reducing injuries due to pedestrian head impact. Research efforts are recommended which include increased collection of accident data, development of vehicle features to protect the pedestrian's head at higher impact speeds, optimization of vehicle front profile and stiffness, increased reconstruction of real accidents, and investigation of protection compatability of adult and child pedestrians. These various studies resulted in the design of pedestrian protection features of Peugeot and Renault experimental safety vehicles.

EXPERIMENTAL SIMULATIONS OF CAR-TO-PEDESTRIAN COLLISIONS WITH VW-PRODUCTION CARS. RESULTS

Results are reported of experimental simulations of car-to-pedestrian collisions which involved impacting a 50th percentile male dummy by three Volkswagen production cars (Golf, Passat, Micro-Bus) at speeds from 35 Km/h to 50 Km/h. The 90 degree position (walking straight ahead) was simulated. The experimental equipment and procedure are described. Kinematic and load data on the dummy are tabulated, and figures illustrate the movement of the dummy head relative to the various vehicles. These tests represent an initial step in determing vehicle modifications for improved pedestrian protection.

PEDESTRIAN PROTECTION: SPECIAL FEATURES OF THE RENAULT E.P.U.R.E. (ETUDE DE LA PROTECTION DES USAGERS DE LA ROUTE ET DE L'ENVIRONMENT) (EXPERIMENTAL SAFETY VEHICLES)

Experimental studies and mathematical simulations of car-to-pedestrian collisions which were undertaken in the development of pedestrian protection features of the Renault E.P.U.R.E., an experimental safety vehicle are reported. The research which was designed to reduce the severity of head-vehicle and leg-bumper impacts, resulted in the decision to cover the windshield frame with an energy-absorbing material shaped for compatibility with the E.P.U.R.E.'s aerodynamic features. This feature provides good protection for the head at impacts of 25 Km/h. The zone encompassing the hood, fenders, scuttle, and lower windshield cross member of conventional cars was redesigned. Improved protection was achieved by the following modifications: a hood that covers the bottom cross member of the windshield, the scuttle, and the fenders; a space to allow for deceleration between the hood and the structural and mechanical components underneath; and optimization of the hood stiffness to make best use of the deceleration distance (good head protection provided for impacts of 30 Km/h. The bumper was shaped so as to lower the point of impact on the legs, thus reducing the frequency of contact between bumper and knee.

IMPROVED PEDESTRIAN PROTECTION BY REDUCING THE SEVERITY OF HEAD IMPACT ONTO THE BONNET (HOOD)

Simulation experiments of car-to-pedestrian collisions using a 50th percentile male dummy and the Audi 100 passenger car are reported. Test results indicate that up to an impact speed of 35 Km/h (50% of pedestrian accidents occurring at or below this speed), adult pedestrians are adequately protected from critical injuries in a frontal collision. For higher impact speeds (up to 50 Km/h), the protection offered by the car front is inadequate. At higher collision speeds, the greatest pedestrian risk is head impact with the hood. In view of these findings, structural modifications were made to the Audi 100 hood to reduce its stiffness and increase its energy-absorbing capacity. These changes are described, and results of impact tests of the modified design are provided which show a 50% reduction in mean impact decelerations, thus considerably reducing the severity of forces to which the skull is subjected. The design modifications will be incorporated with only minor changes in the body design of the next Audi 100 model as a first step towards a systematic effort to improve pedestrian protection.

PEUGEOT VLS 104 AND PEDESTRIAN PROTECTION (EXPERIMENTAL SAFETY VEHICLE)

Accident data analysis was undertaken to define research objectives for the development of pedestrian protection features for the Peugeot VLS 104, an experimental safety vehicle. Computer simulation studies of pedestrian trajectories in frontal collisions are outlined, as well as dummy head free-fall impact tests, and leg/bumper and pelvis/hood-front impact studies using a pendulum test device. Modifications are described which were made to the hood, fenders, grille, windshield wipers, windshield and its frame, and vehicle front to decrease stiffness and improve energy-absorbing capability. Favorable results are reported from tests of the design changes; the risk of severe injury in the case of 40 Km/h car-to-pedestrian collisions has been demonstrated. It is indicated that the head/vehicle impact speed has been decreased from 14.5 m/sec to 13 m/sec. Bumper tests demonstrated the compatibility of the design in terms of pedestrian and vehicle protection. The design modifications account for a 3.8% increase in cost, and 1.4% increase in weight of the vehicle.

VEHICLE DESIGN FOR PEDESTRIAN PROTECTION

The design of a modified production vehicle (1978 Pontiac LeMans) for improved pedestrian protection through increased vehicle surface compliance is described. This vehicle was selected primarily because it has a molded, flexible fascia forming the exterior of the hood edge and bumper. A pedestrian-injury-reduction design was incorporated by installing specially developed energy-absorbing foam materials (developed in conjunction with Davidson Rubber Co.) in the space behind the flexible exterior fascia and the radiator yoke panel. The rigid, metal bumper structure was replaced with resilient foam elements. Results are presented of the experimental evaluation of the modified design using 5 mph barrier impacts, and eight pedestrian impacts using adult and six-year-old-child dummies. The results indicate that a substantial reduction in pedestrian injuries is possible through straightforward modifications to existing production vehicles. The new design also offers a weight savings.

DEVELOPMENT OF A SIMPLIFIED VEHICLE PERFORMANCE REQUIREMENT FOR PEDESTRIAN INJURY MITIGATION

As part of the National Hwy. Traffic Safety Administra
research program to establish the feasibility and practicabil
modifying vehicle exterior structures to improve pedestrian
tection, work is described in the development of a comp
test and methodology for vehicle fronts in terms of pede
leg injury. A local impactor for propelling a 7 lb leg fo
bumper speeds up to 30 mph was designed and built. A se
tests were performed to adjust the impact characteristics
leg form to achieve the best duplication of maximum forc
time to the peak observed in cadaver tests. It was found th
leg form can simulate the dynamic interaction of a pede
leg with the front of a vehicle; that the response of the leg
when impacting a vehicle has a relationship with the sever
the injury produced; and that limiting the response of th
form through vehicle front modifications does reduce pede

trauma. It was determined that by limiting the maximum leg acceleration to less than 100 g's during a 25 mph impact, a protective concept would comply or appear to comply with a standard based on these tests.

CONSIDERATIONS IN THE DEVELOPMENT OF A PEDESTRIAN SAFETY STANDARD

In the National Hwy. Traffic Safety Administration's research program to establish the feasibility and practicability of modifying vehicle exterior structures to improve pedestrian protection, four tasks comprise the Federal Motor Vehicle Safety Standard (FMVSS) development process: preliminary analysis of the U.S. pedestrian safety problem to establish a need; countermeasure development (examining the relationship between collision parameters and pedestrian injuries through vehicle testing with dummies and cadavers, and determining vehicle modifications to reduce pedestrian injury severity); development of the methodology and performance criteria for simulation and evaluation of the vehicle modification countermeasure; and an effectiveness analysis to evaluate the injury-reduction potential of the countermeasure. The proposed maximum allowable acceleration for the lower leg simulator is 100 g's, 60 g's for the child upper torso, in 25 mph impacts, using the developed procedure (striking vehicle at bumper and hood edge with body segment impact simulator). The proposed pedestrian impact protection standard is compatible with other standards with the possible exception of Part 581, (Bumper Standard), and FMVSS 208, (Occupant Crash Protection). The new requirements are not expected to keep a complying vehicle from meeting the requirements of these standards.

INTEGRAL OR COMBINED BRAKING SYSTEM FOR MOTORCYCLES

An integral braking system for motorcycles which has combined control of the front and rear brakes is described. In this system, the pedal operates one front brake and the rear brake, while a hand control operates a second front brake which is employed as an emergency brake or correcting device in cases of extremely violent braking. The system also has a pressure-limiting valve sensitive to high load differences. The integral system provides automatic distribution of the braking forces. The right hand is left free to regulate the throttle control, thus contributing to driving safety. The system provides maximum efficiency in braking, avoiding front wheel lockup under all conditions.

IMPROVING THE STABILITY OF A COMMERCIAL VEHICLE WHEN BRAKED

The association between wheel locking and loss of directional stability during braking, and the need for careful control of braking imposed at each axle of a commercial vehicle are briefly discussed. The matching of braking distribution to adhesion available at each axle is examined. Mechanical linkages and expander mechanisms of conventional heavy-truck brakes (i.e. drum brakes) contribute to braking performance unpredictability. The multi-disc brake concept is explained as a means to reduce the braking problems associated with commercial vehicles. The advantages of the multi-disc brake are direct fluid pressure actuation, giving predictability and low operational hysteresis; frictional consistency; and the avoidance of heat distortion and poor maintenance problems, together with the favorable characteristics of disc brakes, hitherto limited to passenger cars. The viability of this concept in commercial vehicle applications is mentioned as being heavily dependent upon the advanced materials technology of the aircraft braking industry.

HYDRO-AIR BRAKE SYSTEM

A conventional commercial vehicle air brake system was modified by separating the control and energy delivery functions in an effort to minimize the delay between control movement and brake application for improved stopping distances. A minimum number of components connected with the control function were changed. The conventional foot-brake valve and relays were replaced by direct acting relays, placed as close as possible to the brake actuators for minimizing compressed air travel distance. Hydraulically triggered relays, rather than mechanical linkages, were utilized for ease of packaging. This Hydro-Air Brake System achieves optimum response time without compromising the packaging of the piping system to the driver's foot pedal. The system has been applied to both a 16 ton truck and a 38 ton tractor trailer. Comparative data for conventional and hydro-air systems confirm the significant reductions in application delay and stopping distance. The tractor trailer system is fully compatible with European standards and conforms to the requirements of Directives 71/320/EEC and 75/524/EEC. No change in trailer braking characteristics are associated with application of the Hydro-Air Brake System to the tractor.

AUTOMATIC BRAKING SYSTEM. A STUDY (AUTOMATIC COLLISION AVOIDANCE SYSTEM)

Target discrimination of a short-pulse modulation microwave collision avoidance radar system with microprocessor-based electronic circuitry installed in a car was evaluated in road tests. A restricted radar detection range, imposed by the steering wheel angle, was found to be effective in reducing false target detection, a common problem in studies of automatic collision avoidance systems. Proving ground tests were conducted of the radar system coupled with the vehicle braking system. Correct timing of brake application to avoid collision with a metal pole was found to occur throughout the tests, under various closing speeds and road surface conditions. There were rare instances of minor collisions with the pole caused by fluctuation of the road surface friction coefficient.

RADAR-CONTROLLED FUNCTIONS IN THE U.S. RESEARCH SAFETY VEHICLE (RSV)

The radar-related subsystems are described which were used in the high-technology version of the Research Safety Vehicle (RSV) developed under Dept. of Transportation sponsorship. An FM/CW radar, interfaced with a microcomputer, provides collision-mitigation braking, automatic safe headway control, and driving-related warning messages. The collision-mitigation function of the RSV involves the application of antiskid brakes when radar and other sensor inputs indicate that a collision will take place. The radar processing hardware and associated computer algorithm for this function is optimized with the aid of tape recordings of a large number of different road, traffic, and weather conditions. Separate road tests are used to demonstrate the reaction time of the system in a simulated collision with an expendable target. The headway control system, interfaced with the throttle of the car, permits the keeping of a safe distance behind the lead car, based on the radar's range and range-rate inputs. A warning message appears on the electronic display if the actual distance becomes less than the safe limit. The system, when perfected, is expected to improve safety and fuel economy.

POSSIBILITIES FOR IMPROVING SAFETY WIT THE DRIVER-VEHICLE-ENVIRONMENT CONTR LOOP

Three major phases in the sequence of events leading to a tr
accident are described, including the role of the driver, veh
and environment in each phase: normal ride (enough time
space to avoid an accident); initiation of an accident-avoid
maneuver, e.g. braking, lane changing, (accident could be av
ed by adjusting the type and/or intensity of maneuver);
accident no longer avoidable owing to limited tire-road a
sion, even with extreme maneuvering. For a certain in
speed, the relationship is examined between the time of in
braking maneuver and the necessary mean deceleration to a
an obstacle. The effect of an early driver action on acci
prevention is quantitatively studied for three types of accid
for which statistical data on relative collision speed are av
ble: intersection accident, rear-end collision, and head-on c
sion. The time at which braking would have to begin to a
an accident is first established depending on the relative c
sion speed. This time is subsequently compared with the
quency distribution of the collision speed. It is found that
proximately half of all these collisions could be prevente
each driver would initiate his accident-avoidance maneuver
half to one second earlier. A quantitative analysis shows
vehicle technological improvements to effect a 10% increa
the maximum deceleration due to braking or a 10% increa
lateral acceleration in a lane change maneuver would co
spond to driver action advanced at most by a few tenths
second.

VEHICLE CHARACTERISTICS DESCRIBING THE STEERING CONTROL QUALITY OF CARS

Measurements related to steering control quality are presented for 14 European 1978 and 1979 passenger car models (front-end rear-wheel drives). The differences between the measured vehicles are relatively small with lateral accelerations corresponding to normal driving in traffic. With high lateral accelerations corresponding to drastic maneuvers, the differences are very great, in certain cases. Some vehicles require a noticeable change in driver behavior during control with high lateral accelerations, if stability is to be retained. The vehicles have only been measured in a weight condition corresponding to the weight of the vehicle and two occupants. In cases of increased load, an even larger spread of measured results can be expected as increased load, in general, moves the center of gravity rearwards in the vehicle, thus increasing the side slip angle of the vehicle. Several measuring methods are apparently needed to describe the driving characteristics of the vehicle. New passenger vehicles still show relatively large differences in driving characteristics, especially in situations with high lateral accelerations.

DEFINITION OF THE VEHICLE DYNAMIC CHARACTERISTICS BY THE TRANSFER FUNCTION: CORRELATION WITH SUBJECTIVE EVALUATION

Research on vehicle directional dynamics (handling performance) is described which was designed to correlate subjective ratings and vehicle-measured response parameters, and to compare experimental and theoretical results to check the validity of the vehicle model. On a proving ground, five expert drivers drove an instrumented Alfa Romeo Giulietta in six different configurations of weight distribution and tire inflation pressure. Particular attention was paid to the effect of vehicle speed. The drivers applied a random steering input. For lateral acceleration less than 0.4 g, the "random steering input" procedure gave the same results, in terms of yaw transfer function, as other "open loop" tests (such as step input). This procedure proved to be reliable, quick, and simple. The yaw transfer function parameters, obtained by fitting the experimental results to a simple vehicle model (yaw and sideslip), are in good agreement with theoretical ones both in the absolute value and in speed sensitivity. The greatest limitation of the simple mathematical model is reduced agreement between experimental and theoretical phase lag diagrams. The correlation between subjective rating and the yaw transfer function parameters (regression analysis) is considered satisfactory and encouraging. Further research on a larger sample of vehicles and evaluators is necessary.

THE EFFECT OF IMPROVED VEHICLE DYNAMICS ON DRIVERS' CONTROL PERFORMANCE

A four-wheel steering system was examined as a means of further improving the controllability and stability of the vehicle part of the driver-vehicle-environment system. As a result of the analysis of the four-wheel steering vehicle's open-loop characteristics using a mathematical model, it was concluded that the controllability and stability of the vehicle could be improved. Based on this presupposition, the Course Tracking test simulating normal driving, and the Sudden Lane Change Maneuver test simulating evasive maneuver were both applied to the test vehicle in which the steering gear ratios of front and rear wheels can be independently changed on a lateral motion simulator. Both tests proved that the driver was able to improve his control of the vehicle to a remarkable degree when appropriate positive values were selected as the gear ratios of rear to front wheels.

IMPROVEMENT OF REAR AND FRONT LIGHTING SYSTEMS FOR MOTOR VEHICLES

When the reaction time of drivers in a traffic queue was measured in dynamic driving tests using additional high-mounted brake lights on the lead vehicle, it was found that the additional lights greatly reduced the drivers' reaction times. For the last driver in the line of five vehicles, about a 40% reduction in reaction time was realized, both in daylight and nighttime driving. It is concluded that equipping every 5th or 6th vehicle with the additional high-mounted brake lights would be sufficient. A year-long experiment in Washington, D.C. is reported in which the accident rates were determined for three groups of 525 taxis each (one with conventional brake lights, the second with one additional high-mounted brake light, and the third with two additional high-mounted brake lights). The use of one additional light reduced the accident rate by 54%. The reason for a smaller reduction with the two additional lights was related to the combination of brake light and directional signal. Dynamic driving tests are also reported which evaluated the use of a supplementary motorway low beam with the conventional headlamp low beam. A gain in visual range of 50% to 100% was found with the combined system, with only an insignificant increase in glare.

AN OPTIMUM VISIBILITY DESIGN FOR THE STOP LAMP (BRAKE LIGHT)

The luminous intensity distribution of a brake light was optimized to improve glare reduction and visibility. The discomfort from glare of some prototype lamps was evaluated in the laboratory under simulated night conditions, as well as in actual day- and night-time driving. Outdoor stationary experiments of long-distance visibility under daylight conditions, and day and night visibility evaluations were conducted in road tests. These tests showed that, with clear weather conditions, the brake lights are visible at a distance of over 1000 m (either day or night), and that the glare at night is acceptable even at short distances. The light must be positioned lower on the vehicle body, and must be photometrically aligned in the vertical plane. A modification to present Economic Commission for Europe regulations to allow installation of this new lamp could contribute to driving safety.

A PRACTICAL APPROACH TO REAR UNDERRIDE PROTECTION

The development of an energy-absorbing underride protective device for trucks is described. The unit consists of a horizontal bumper beam supported by specially designed drop arms. The arms are hinged and supported by energy-absorbing struts using a geometry where specially developed hydraulic cylinders form one side of a triangle, the bumper beam being attached to the extensions of the drop arms. For the hydraulic cylinders, the theory of fluid energy absorption using variable flow control orifices was applied. The novel approach in the underride guard's design is the method of controlling the hydraulic damping force, which is provided by the passage of fluid through an orifice formed by a slot in a liner between the piston and the cylinder wall. The shape of the slot determines the characteristics of the energy absorber. When the latest version of the device was evaluated in full-scale impact tests at 30 mph, results indicated that the car occupants would have been only slightly injured and that the underride guard suffered no damage. The design of the unit does not reduce the truck's ability to negotiate steep ramp angles, and reduces the effects of impact with a roadway obstruction. A sensor in the device activates braking when the reversing truck contacts an obstacle. The system is so sensitive that only 30 kg (66 lbs) force on the beam can stop a fully laden truck and trailer within 75 mm. Weight reduction of the underride guard is currently being investigated.

INDIRECT VISIBILITY REQUIREMENTS FOR PASSENGER CARS

An investigation of a design concept for the rearview
system in Japanese automobiles was undertaken from th
point of human factors, such as real traffic conditions,
dimensions, driver's characteristics (e.g. distance
mirror monitoring patterns, mirrors as an obstacle to
visibility, and subjective evaluations), and various geome
tors. It was determined that convex mirrors with 900
mm radius of curvature are the most effective outside
mirrors. The passenger's door mirror is too far from the
lar fixation field. The outside mirror on the driver's si
provide a field of vision (FOV) enabling the driver to se
m wide plane at 4.60 m behind him. For the inside
mirror, 8% reflectivity is preferable on the night positio
two-position prismatic mirror. The center of the inside
must be located not less than 5 degrees inside the b
FOV. The inside mirror should not be less than 300 m
from the driver's eyes, its right edge at a horizontal a
less than 25 degrees away, and its lower edge at a vertic

not less than 2 degrees away. The fundamental FOV of the inside mirror is 3.6 m binocular (6.7 m ambinocular) width at a distance of 15 m behind the car.

U.S. MOTOR VEHICLE SAFETY IN PERSPECTIVE

Motor vehicle travel and highway casualties, including pedestrians, in the U.S. are reviewed for the period between 1945 and 1977. The number of traffic fatalities per unit travel in this period has been reduced by a factor of two to three, as a result of improvements in the highway network, in motor vehicle equipment, driving conditions, driver education and other factors. More specifically the safety record of motor vehicles is reviewed by an examination of accidents and of occupant fatalities and injuries in passenger cars and light trucks as a function of model year, based on U.S. accident and casualty experience in each of the three calendar years 1975, 1976 and 1977. Evidence of improvements is manifested as a reduction of fatality and injury risks by 40% to 50% between pre-1969 and post-1974 model years. These and other improvements are examined in the context of Federal Motor Vehicle Safety Standards. Areas where a high effectiveness has been expected but not observed are particularly emphasized and countermeasures either mandated for near-term effectivity or planned for the future are discussed with a sense of priority. For added perspective, progress is also reviewed in the areas of pollution control and fuel economy improvements. The resulting impacts on the consumer and on the manufacturers are examined in view of allegations that the regulatory programs mandating safety, air quality and fuel economy improvements have been unduly costly to the consumer and too burdensome to the motor vehicle manufacturers.

AMERICAN ASSOCIATION FOR AUTOMOTIVE MEDICINE ANNUAL CONFERENCE (23RD) PROCEEDINGS, LOUISVILLE, KENTUCKY, OCT. 4-6, 1979

Thirty-nine papers are presented on a wide range of topics concerning highway safety. Among the issues addressed are seat belt (including passive restraints) and child restraint legislation, seat belt and child restraint performance and evaluation, occupant protection (interior impact) legislation, collisions of motor vehicles with pedestrians (children, persons affected by alcohol), the influence of drugs and alcohol on drivers, motorcycle accidents, driver performance and licensing (medical advisory board), steering wheel impact injury, and roadside safety devices. Also addressed are statistical models of policy analysis, staged collisions (Calspan Reconstruction of Accident Speeds on the Highway 2, and Simulation Model of Automobile Collision computer programs), side impact, mature drivers, driver inattention, school bus safety legislation, accident exposure, and crash and injury studies.

A COMPARISON OF ALCOHOL INVOLVEMENT IN PEDESTRIANS AND PEDESTRIAN CASUALTIES

A 1975-1976 field accident research study was conducted in New Orleans, La., to determine the percentage and relative risk of alcohol involvement in adult pedestrian fatal and injury accidents; to identify any unique accident types, behavioral errors, or other characteristics that distinguish these accidents from non-alcohol pedestrian accidents; and to study the alcohol use patterns and the drinker classifications of these pedestrians. Extensive data were collected on adult (age 14 or over) pedestrian fatal and non-fatal accident cases, and control groups were established, based on accident and random site sampling. Results indicate that the degree of alcohol involvement in non-fatal crashes is as great as in fatal crashes, with high blood alcohol concentration (BAC) recorded in a surprisingly large proportion of both groups. When pedestrians with a positive BAC were compared with controls matched by site, by age/sex/site, and at random, the risk of accident involvement was found to increase at a BAC of .10% and to accelerate rapidly at higher BAC levels. Although no significant differences were found in accident types, behavioral errors, or predisposing factors between alcohol-involved pedestrians and controls, there were indications that the path chosen by the pedestrian for crossing a road, the culpability of the pedestrian, and the frequency of the pedestrian striking the vehicle were related to the pedestrian's BAC. The results are discussed, including implications for countermeasures and recommendations for further research.

SEAT BELT LEGISLATION

Mandating seat belt use has been shown in many jurisdictions to be the most effective immediate way of significantly reducing death and severe injuries resulting from motor vehicle collisions. Historically, tort law has played an important role in deterring certain types of conduct. It appears that if the common law continues to develop by itself, the seat belt defense will be increasingly recognized by the courts in assessment of contributory negligence. If seat belt defense is to be recognized by law, such statutes should be broad rather than restrictive to provide just penalty for unreasonable behavior on the part of an individual by which he contributes to injuries caused him by someone else's negligent acts (i.e., contributory negligence). Canadian legal cases are cited where the award was reduced because of the plaintiff's failure to wear a seat belt, as well as other cases where the seat belt defense was not recognized by judges. Expert evidence is often relied upon to provide a causal connection between failure to wear seat belts and extent of injury.

RESIDUAL CARDIOVASCULAR DAMAGE RESULTING FROM NONPENETRATING STEERING WHEEL IMPACT

In an effort to determine whether drivers with accident experience had a significantly different frequency of electrocardiographic abnormalities than their counterparts, two accident victim cohorts and a third matched accident-free cohort were identified and evaluated. These data suggest that many otherwise healthy drivers frequently suffer an insidious subclinical alteration in electrocardiogram (ECG) patterns. Whether thoracic trauma predisposes an individual to eventual cardiac pathology remains unknown; however, these findings confirm the necessity for increased vigilence and consideration. A detailed epidemiologic analysis of extensive data with conclusions is presented. In present practice, little attention if any is given to possible cardiac involvement, especially in the absence of specific symptoms. In the absence of broken ribs, thoracic trauma is often ruled out. Previous studies have indicated that heart damage may not be recognized immediately because of more dramatic physical injuries, and because some "trauma related" cardiac disorders are transient and other more severe cardiac irregularities are reversible. It was concluded from the study that cardiac damage from bodily trauma is variable and unconnected with age or type and extent of injury. Cardiac damage can occur without fracture to the ribs and/or the sternum. The statistically significant increase in electrocardiographic abnormalities in persons subjected to blunt thoracic trauma supports the hypothesis that cardiac damage results from such trauma. The study results also indicate that electrocardiographic abnormalities will be discovered by repeated ECG tracings at intervals soon after the accident. This early recognition is important to minimize complications and to prevent more serious aftereffects, although nonpenetrating thoracic trauma seldom produces serious consequences unless the myocardium is ruptured or fatal arrhythmias develop. The study sample was too small to make any definitive evaluation of the effectiveness of the collapsing steering column in preventing heart damage.

PROFILES OF FATAL COLLISIONS INVOLVING CHILD PEDESTRIANS

An investigation was made to examine the characteristics of
child pedestrian fatalities. The study sample was divided
three groups of victims, age 1-4, 5-7, and 8-14; analytic
distinct profiles or collision typologies were produced for
group. Pedestrians age 1-4 were found to be involved dispro
tionately in daytime collisions occurring on or near pri
driveways; frequently the child was run over by a motor v
cle which had been set in motion from a parked position. Pe
trians age 5-7 were involved disproportionately in collis
occurring in the hours immediately preceding or follow
school. Such victims tended to be crossing the roadway f
behind a parked car. Children age 8-14 were disproportiona
involved in collisions at night. Frequently, the victim was str
while walking along the highway or when crossing at an in
section. Driver error was apparently not a factor in two-th
of these accidents. Recognition of these differences in charac
istics of fatal accidents is important for developing appropr
countermeasures. Among the recommended actions are desi
ing systems or programs to improve the conspicuity of yo
children (age 1-4), to develop improved and earlier safety e
cation for school children (age 5-7), and to improve night v
bility for older children (age 8-14).

A PROTOTYPE LOAD-SENSING DUMMY FACEFORM TEST DEVICE FOR FACIAL INJURY HAZARD ASSESSMENT

Neither headforms nor dummy heads are currently capable of adequate assessment of localized loadings likely to cause serious disruption of the facial structure. Some interior design concepts, while performing adequately under the Federal Motor Vehicle Safety Standard 201 test conditions, can cause serious injury to passengers' faces, even at relatively low interior impact speeds. The design and preliminary testing of the face-force prototype headform concept is described, incorporating load-sensing elements capable of evaluating facial bone fracture hazard by measurement of localized forces in dynamic frontal loadings, yielding a force-time history in each region of interest. The device can be rugged enough for repeated use, and is compatible with other dummy uses. The faceform was designed and mocked up for incorporation in a Part 572 dummy skull. It employs damped cantilever-beam supports whose root strain is measurable electronically and directly related to the peak tolerable loads over a structural section of the human face. The mock-up has been sized for four facial areas: nasal bones, zygoma-suborbital regions (left and right), and maxilla/mandible area. The force-measuring principles employed could be adapted to up to eight areas within the face, if desired. Prototype testing on a bench-model sensor has demonstrated that such a faceform concept is workable. The device employs off-the-shelf strain gauge transducers and straightforward production techniques. Total additional cost for a production dummy head so equipped would be less than $400, exclusive of the research and development work required to prepare it for production.

FATAL ACCIDENTS IN THE FIRST FIFTEEN MONTHS OF THE NATIONAL CRASH SEVERITY STUDY

The National Crash Severity Study (NCSS), a project of the National Hwy. Traffic Safety Administration, collects crash-related data for a rigid sample of accidents within eight sampling areas. An investigation was made of the fatalities for the first 15 months of NCSS, which includes towaway, passenger car accidents. Important factors associated with higher fatality rates were identified and quantified using fatality rates (as found in the file) and modeling techniques (for the separation of correlated factors). Higher fatality rates were computed for accidents involving a single vehicle, a rural setting, large changes of velocity at impact, direct impacts, rollovers and side impacts, and various occupant factors. In particular, occupants sitting in the front seat or near a window, the older occupants, males, ejectees, and unrestrained occupants had higher fatality rates than did occupants without these characteristics. Rollover and ejection, which often occur together, are each independently associated with a higher rate of fatality. Of the two factors, ejection appears more related to a higher probability of fatality than does rollover alone. Further analysis is needed to determine which of these factors are causes of fatality and which are merely indications of the severity of the crash.

DRIVING TESTS UNDER THE EFFECTS OF BETA RECEPTOR BLOCKING DRUGS

Twenty healthy subjects were used in a double blind study to test the two beta receptor blocking drugs, propranolol and pindolol, with respect to their effect on drivers and driver behavior. The driving tests were conducted on a test track. In addition to several psychophysiological parameters and psychomental performance tasks, driver behavior was studied by means of special auxiliary driving tasks. Apart from the effects on the heart and circulation system, predicted on the basis of the pharmacodynamics of beta blockers, a clear change in psychophysiological reactions was established. Beta blockers have a negative effect on psychomotor coordination and reactivity. These results, together with the sedative side effects reported by many subjects, are interpreted as a general reduction of activation due to the ingestion of beta blockers. Specific clinical findings include slower heart rate, although there were variations under different load conditions; loss of the anticipatory effect in the electromyogram; and lower skin conductance level and response. Performance characteristics include impaired concentration and mental performance; increase in reaction times; change in psychomotor ability (coordination in driving a circular course); and increase in subjective feeling of fatigue. In some individuals, an improved performance was noted. Effects of long-term therapy with these drugs could not be determined in this study.

EFFECTS OF PEDIATRIC EDUCATION ON THE USE OF CHILD RESTRAINT DEVICES IN NORTH CAROLINA

Two observational surveys were conducted at a one year interval to determine if an educational campaign focusing on pediatricians had been able to increase the use of automobile child restraint devices in selected North Carolina cities. Although usage rates were higher for the follow-up survey, little if any of this increase could be attributed to the educational campaign. It was further determined that possible benefits of higher usage rates for these restraints may be negated by continued high rates of misuse of the restraints by parents. It can be concluded that there does exist a "follow-the-leader" effect in restraint usage such that if parents can be convinced to use restraints for themselves, they may also better protect their children. Conversely, while current data cannot document it, it may also be that increases in adult usage might also result from a well-designed child protection education program.

INDICATORS OF DRIVER INATTENTION

Traffic accident investigations have shown that some form of attentional failure is a common causal factor in traffic accidents. An overview of the literature suggested four basic attributes, or dimensions, of attentional performance: intensity; distribution; regularity; and mode of control. The indicators of attentional performance have been discussed in two major groups, behavioral and physiological. Behavioral indicators include: drivers' self-assessments of fatigue and alertness, observers' judgments of attention-related driving errors, driver-vehicle performance as measured through vehicle dynamics, drivers' looking behavior (including eye movements, pupil size, and blinking), and performance of non-driving tasks. Physiological indicators include such measures as heart rate and its variability, skin conductance and electrodermal response, and brain and muscle electrical activity. No single measure has been identified which reliably and unequivocally indicates inattention. Under normal conditions, drivers monitor their own attentional performance, and adjust their behavior to what they perceive to be the attentional demands of the task, although little is known about the cues used to assess their own state of attention and what can be done to improve it.

THE NEW MICHIGAN DRIVER PERFORMANCE TEST

A three-phase study of Michigan's driver license road test was initiated in 1974 and completed in 1977. A pilot implementation of a new Michigan Driver Performance Test (MDPT) has begun, involving four major tasks: the redesign of prior MDPT training materials and development of road test route materials for more efficient and broader use in preparing 12 instructors to develop special MDPT road test routes and train examiners, and in instructing 12 driver examiners to use the MDPT and test route; the selection of road test routes at pilot implementation sites that were representative of the traffic environments in that locality; the pilot implementation of the MDPT in three different sites typical of those examining offices or bureaus serving Michigan's rural, urban, and metropolitan areas (Howell, East Lansing, and Flint); and the implementation and observation of the training programs developed for the instructors and driver examiners. Among the results observed early in the program were increased examiner morale, favorable response by public to the feedback, and more factual and useful information provided to applicants regarding the kinds of practice needed to drive and reduce hazards. Pilot implementation at each site was followed with periodic monitoring of the MDPT program.

PASSIVE PROTECTION: PROMULGATION OR POLITICS

The subject of occupant crash protection remains a political cause celebre, with powerful adherents to either side of the belt/bag controversy and a mountain of printed rhetoric. More research is needed to give full assurance of safety of air cushion systems in the areas of small child static deployment injuries, sodium azide toxicity, and diminished adult injury tolerance. On the other hand, there remains the lack of voluntary use of active shoulder belt systems. Only one "passive" restraint system has seen extensive acceptance and use as a true user option. The Volkswagen Rabbit passive belt/knee bar is an outstanding example of design initiative that is yielding excellent benefits and relatively high usage. Among the air bag design options, one system holds the multiple promise of significant and early safety benefits at reasonable cost, while minimizing exposure. An air bag plus active lap belt for the driver only, and a passive belt and knee bolster for right front passenger, together with conventional active/passive belt and warning systems for the remaining seating positions, clearly offer the greatest protection at the least cost of all viable alternatives for large cars. This configuration also presents the unique prospect of large-scale, real-world experience, which is the only real way to answer many of the nagging questions about restraints effectiveness. While it is noteworthy that any 30 mph passive system in broad implementation can probably save about 27% of the "Top-20 Modes" casualties (19.2% of all occupant casualties), further progress appears to be possible, particularly for driver protection. This will only be achieved after the first implementation step is taken, one which the consumer, not just government and the manufacturer, is willing and able to take. The current full-front-seat passive requirement carries with it the danger of consumer backlash because of some side effects of large, vented passenger air cushions. Relaxation of the passivity requirement for the center front seat position would permit greater flexibility in restraint design without reducing the number of automobiles equipped with driver air cushion systems. It would further permit orderly transition into full production, while providing good measures of relative effectiveness of various systems and impetus for a diversity of consumer-choice options.

OCCUPANT RESTRAINT SYSTEM MODELING USING THE MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL OCCUPANT DYNAMICS MODEL

Applicability of the MVMA-2D Occupant Dynamics Model originally developed for the Motor Vehicle Manufacturers Assoc. by the Univ. of Michigan Hwy. Safety Res. Inst. in 1974, has been improved by the introduction of new computer routines which facilitate visual evaluation of the computed results by displaying kinematics of both the occupant and vehicle interior in computer-generated movies. These displays can demonstrate simplified deployment kinematics of inflatable restraints, restraint belt action, occupant neck and shoulder movement, and passenger compartment intrusion. New techniques permit onboard and offboard views of the crash sequence, and one-step processing speeds up the generation of kinematics graphics and movie. The program also provides computer plotting of all output variables for purposes of documentation and identification. To document the practical application of these computer routines, the new developments are demonstrated in simulation of five 48.3 kph (30 mph) frontal barrier crashes which compare the effects of no restraint, lap belt restraint only, lap and shoulder belt, inflatable restraint only, and the inflatable restraint and lap belt combination. Critical response data for analysis in this mode-of-restraint parameter study are presented in a computer drawn relative-performance "star chart" which identify significant elements in a specific crash for quantitative comparisons. In the demonstrated form the improved model clearly represents a superior means to provide additional information for automotive design guidance.

THE BIOMECHANICAL LIMITS OF SEAT BELT PROTECTION

A study was conducted to define the biomechanical limits of the protection afforded by current seat belt systems and to describe the nature of the injuries sustained. Particular attention is given to those body areas where loading from the belt itself can cause injury. The results presented are based on a retrospective in-depth field study of occupants who were using three-point belts. The accident sample consists of about 650 restrained occupants, most of whom were involved in frontal impacts. For the head and face, the steering wheel is the major source of injury for drivers. For the chest, three main compromising factors are identified: intrusion into the passenger compartment; additional loading from behind; and occupant age. The progression of chest injury severity, from bruising, through single and multiple rib fracture to thoracic organ injury can also be illustrated. The pattern of rib fracture shows that the ribs loaded directly by the belt, particularly the lower ribs, fracture first. Lower rib fracture can also lead to abdominal organ injury from the diagonal section of the belt. With European belt systems, injuries from the lap section have been largely eliminated; injuries from the diagonal section can limit current belt system effectiveness against abdominal injuries. Results of the study are discussed with reference to human tolerance and current test procedures. The two most important factors limiting restraint performance are intrusion and additional rear loading, without which restrained occupants rarely sustain life-threatening injuries. It is noted that the distributed frontal barrier test is not particularly representative of real-life accidents, especially as concerns intrusion. Lack of test information precluded estimates of cases involving under-run, which usually involves high-level intrusion. Seat belt restraint efficiency in side impacts was noted. The effectiveness of frontal impact dummies in evaluating side impacts is questioned, since the dummies appear to slip out of the diagonal section of the belt. It is noted that injury criteria are not needed for the neck and abdomen with current restraint systems and that femur criteria seem inadequate as the sole assessment of leg injury potential, since a significant portion of leg injuries involves injury beneath the knee.

IS FURTHER LEGISLATION REQUIRED TO INCREASE SCHOOL BUS SAFETY?

Accident cases involving school buses were studied in depth by the Ecole Polytechnique and McGill University Multidisciplinary Accident Investigation Teams over the past few years. The accident mechanisms, the results, and the causal factors are outlined, with principal focus on design, deficiencies in maintenance, driver training, and attitudes. Existing safety standards relating to school buses are discussed, along with proposed governmental safety standards. The Quebec Provincial Government has formed a Commission looking into bus safety whose main concern is driver training and vehicle maintenance. This task force was appointed by the government to document the numbers of unsafe buses operating within the Province of Quebec, to determine to what degree they are unsafe, to make recommendations for improving the safety of those meeting a minimum standard, and to prevent those determined unsafe from operating in the future. The results of this commission's findings and regulations and methods to improve the school bus mode of transportation are discussed. Principal recommendations made by the Commission to the Provincial Government are included.

PATTERNS OF INJURY IN PEDESTRIAN ACCIDENTS

Data obtained from existing hospital and police records are used to describe the general pattern of injury sustained by pedestrians in Birmingham, England during 1976. It is shown that although head, leg, and arm injuries were the most frequent injuries sustained, the exact pattern of injury was influenced by many factors, such as pedestrian age, vehicle type, location of initial pedestrian contact with the vehicle, and overall injury severity. In general, pedestrians contacting the sides of cars sustained fewer serious pelvic and leg injuries than pedestrians struck directly by the fronts of cars. Pedestrians struck by the fronts of buses or heavy goods vehicles sustained fewer serious pelvic and leg injuries and more serious chest, arm, and head injuries than pedestrians struck by the fronts of cars. Pedestrians struck by motorcyclists generally sustained fewer serious pelvic injuries and more serious arm injuries than pedestrians struck by the fronts of cars. The incidence of serious head injuries decreased and the incidence of serious pelvic, arm, and leg injuries increased with age. The likelihood of injury to any particular body area was found to increase with increasing overall injury severity. Leg injuries were generally more frequent than head injuries for survivors with minor injuries; the converse was true for survivors with non-minor injuries. Although head injuries were the main serious injuries sustained by survivors, many of these caused only short periods of unconsciousness. If these injuries are not considered as serious, leg injuries become the most frequent serious injuries sustained by survivors. Head injuries were the most frequent serious injuries sustained by pedestrian fatalities. Tables are included, showing the body area distribution of injuries by age and accident type for various injury severities.

THE EFFECT OF THE TEXAS MEDICAL ADVISORY BOARD FOR DRIVER LICENSING ON DRIVING PERFORMANCE

Traffic offenses related to chronic medical conditions and the effect of a Medical Advisory Board (M.A.B.) for Driver Licensing are discussed. The accident and violation ratios of 19,110 Texas drivers with medical limitations were studied. Ratios before and after Board review were compared in each category of illness and in each age group and related to the state average. The effect of M.A.B. was good for all categories of illness with the exception of limitations related to psychiatric and addiction disorders. The accident ratio of all drivers with chronic medical conditions improved by 51%; traffic violations improved by 21%. The effect of the M.A.B. review may be explained by a variety of reasons: mathematical regression of the accident ratio; deterrent effect of the action; complete elimination or restriction of the impaired driver from the road, or reduction of the driver's mileage. All of these factors may contribute, but do not fully explain the effect of M.A.B.

YOUTH, ALCOHOL, AND DRIVING: SUBTLE ATTITUDE MEASURES

A series of tests was developed in response to the need for a subtle attitude measure of the effectiveness of formal education programs directed at reducing the frequency of drinking and driving. The tests were generated as the final product of a rigorous and objective process of test development which comprised the following steps: defining criteria, developing preliminary measures, pre-testing, item validation, test refinement, and test validation. The results of this process are a useful obvious measure and useful subtle measures for determining youthful attitudes toward drinking and driving. The obvious test, "Drinking and Driving: What Do You Believe?", is a scaled test of beliefs which can be used when honest answers are expected. Two subtle tests are called "What Are the Facts?", a pseudoknowledge test, and "What's Going On?", a picture interpretation test. These tests can give results when honest attitudes are harder to elicit.

ARE ALL DRIVERS WHO DRIVE AT HIGH RISK? THE ROLE OF EXPOSURE IN DETERMINING THE RISK OF COLLISION

Driver exposure to the risk of an accident is a variable which has been difficult to measure and frequently ignored in epidemiologic studies of traffic accidents. To study exposure, 3000 drivers living in Metropolitan Toronto were interviewed by telephone during 1978, to assess the amounts and types of driving they had done. Drivers had been selected at random from provincial records to include drivers from six different groups: males with 0-2 points, 3-5 points, 6-8 points, or 9 plus demerit points and females with 0-2 points or 3-5 demerit points. (Demerit points are assigned when a driver is convicted of one of 26 traffic offenses.) Women had driven fewer miles than men at the same level of demerit points, for each type of driving (city, highway, rush-hour, night). Within each sex, drivers with more demerit points had driven significantly more than drivers with fewer demerit points. The actual number of convictions and collisions experienced by the sample of drivers was obtained from provincial records. Rates of collision and conviction were calculated using persons and person-miles in the denominator: when account was taken of the mileage, women had higher collision rates than men with comparable demerit points. Furthermore, drivers who typically drove small amounts each week (under 120 miles/week) had a much increased risk of collision per mile, which was even greater if the driver had acquired demerit points. Drivers with greater mileages per week had a relatively low risk of accident per mile which was not altered by the number of points. Results suggest that licensed drivers need to maintain their skills with frequent practice. Low exposure drivers may also have a higher risk because of a greater proportion of city driving, where the combination of intersections, traffic signals, and the like seems to produce a high risk for the inexpert driver.

AN ON-THE-SPOT STUDY OF MOTORCYCLE ACCIDENTS IN NIGERIA

An on-the-spot study of 201 motorcycle casualties in Nigeria showed a high percentage of possession of crash helmets following the crash helmet legislation in the country. Motorcycle accidents consisted mostly of collisions with cars and trucks. Head and neck injuries were the most common type among persons who died at the accident scene; lower limb injuries were the most common type among those taken to the hospital. It is recommended that helmet legislation include specifications for proper wear to ensure that helmets are in place when they are most needed, and that users be informed about the limitations of crash helmet protection. Also recommended are bright wearing apparel, reflective armbands, and daytime use of head lamps to increase conspicuity of motorcyclists and to decrease the risk of collision with other vehicles. Reduced importation of powerful motorcycles is also recommended as a measure for reducing motorcycle crashes.

55 ALIVE/MATURE DRIVING

"55 ALIVE/MATURE DRIVING" has been developed as a community service program for motor vehicle operators age 55 and over. The program is the first comprehensive nationwide course designed to deal with the special interests and needs of this age group. The six-session course includes information which research has shown will help older drivers update driving knowledge, sharpen skills, and remain on the road longer. The six sessions cover the following topics: overview of driver characteristics in the 55 and over age group; physical changes (impairment of vision and hearing, slower reaction time, effect of medication); perception in specific driving environments; rules of the road (right-of-way, intersections, turning, passing, backing, freeway entrance and exit, and lane changing); accident prevention measures, adverse driving conditions, and other road users; and local driving problems and license renewal. The program is currently being pilot tested in California, Florida, Illinois, and Virginia. More than 10,000 older drivers are participating in the project. The effectiveness of the course is being evaluated by the Dept. of Transportation. It is hoped that the program can emerge as a national model for traffic safety officials.

SAFETY BENEFITS OF THE SEAT BELT LEGISLATION AND SPEED LIMIT REDUCTION IN ONTARIO

In Jan 1976, legislation became effective in Ontario, Canada, requiring the use of seat belts. In Feb 1976, the seat belt legislation was enforced for the first time and speed limits were lowered on many of the major highways. The evidence is examined that shows that both seat belts and lower speed limits have been effective in reducing injuries and saving lives. Included are the trends in observed seat belt use, trends in travel speeds, fatality and injury rates with and without belts, accident statistics on highways where the speed limit was lowered compared with highways where the speed limit was not lowered, and fatality and injury rates for vehicle occupants compared with other motor vehicle accident victims. It is concluded that the observed reduction in the fatality rate and in the non-fatal injury rate for vehicle occupants can be attributed to the combined effect of seat belt legislation and the speed limit reduction.

WHO ARE USING CHILD RESTRAINT SYSTEMS AND WHY–DATA FROM FOUR MAJOR CANADIAN CITIES

A report is summarized which was prepared for the Minister of Consumer and Corporate Affairs of Canada on the use and suitability of currently available vehicle and auxiliary restraint systems for the protection of child passengers in crash situations. Information from current literature and selected experts was reviewed on the technical, medical, and some legal aspects of child restraint systems. A study of parents' utilization of car seats or seat belts for their young children was carried out simultaneously in Montreal, Toronto, Calgary, and Vancouver to find out the degree of use as well as the factors related to such use. Telephone interviews were conducted with 902 parents of children aged 6 years and under. Analysis of the questionnaires indicated that the parents could be divided into six groups: those who have a car seat, always use it (32.9%); those who have a car seat, sometimes use it (14.2%); those who have a car seat, never use it (12.5%); those who previously had a car seat (21.5%); those who never had a car seat (15.0%); and those who never heard of a car seat (3.9%). Direct observations were also made of the methods by which child seats have been installed by looking through the vehicle windows in parking lots. Limited information on the performance of child restraint systems in actual collision situations was derived from accident records and reports. It is concluded that more comfortable and more convenient child restraint seats would lead to increased usage. It was found that use of car seats is greatest for children ages 1-2 years and that usage decreases as the child grows older; at ages 4-5 years, the child is considered too large for a child seat. Observations indicated that child seats were often improperly attached (e.g. with tether strap unfastened) in spite of the availability of careful installation instructions. It was noted that car dealers were not generally aware of attachment facilities available in General Motors cars. Recommendations include extension of mandatory use legislation for child seats and harness, and application of the tort law to parents who do not protect their children. Promotion of child safety seats by pediatricians, and rental systems for these devices are also recommended.

MOTORCYCLE RIDER COURSE FEASIBILITY STUDY

Applied Science Associates, in cooperation with the Jefferson County School System (near Denver, Colo.) conducted a large-scale feasibility study of the Motorcycle Safety Foundation's "Motorcycle Rider Course" (MRC). Three evaluation criteria used in the study were instructional effectiveness, administrative feasibility, and user acceptance. The course was offered to students within the secondary school system and adults within the community. Based on five separate tests, it was determined that students do gain significant information and skills. These tests were: Pre and Post Test Scores, MRC Knowledge Test Scores, MRC Skill Test Scores, Motorcycle Operator Skill Tests, and Motorcycle In-Traffic Tests. Administrative feasibility was demonstrated by analyzing staff time/task logs, project cost records, and input/feedback from administrators. A high degree of acceptance was indicated by attitudinal data, and student and parent course evaluations. Possible aspects for revision were identified and a preliminary evaluation plan developed as part of a National Hwy. Traffic Safety Administration demonstration project. Revisions included elimination of on-street sessions and refinement of selected course curricula. The on-going demonstration project, to be administered within a state motorcycle operator licensing system, is designed to determine the crash reduction effectiveness of motorcycle rider education courses. A license applicant will be offered the option of obtaining a learner's permit and volunteering for a motorcycle rider education course, or of preparing for improved skill and knowledge tests on his own

THE EFFECT OF A SINGLE ACUTE DOSE OF DIAZEPAM ON DRIVING-RELATED SKILLS PERFORMANCE

The effects of single acute doses of diazepam were examined in eight male subjects using three performance tasks. The tasks included visual search, visual search and tracking in a divided-attention situation, and information processing rate. All subjects received four treatments averaging roughly 9.0, 4.5, 2.3 and 0 mg. At each treatment session, performance was examined at 12 time points in 23 hours after treatment. Significant impairment was found for eight hours after treatment. The behavioral impairments appeared to be dose-related, although not linearly. Comparison of the effects of diazepam to those of alcohol indicates that tracking ability was about equally impaired by a blood alcohol of 0.07% as by a medium (4.5 mg) dose of diazepam. Response times and combined error scores in the visual search task were larger under alcohol than under the highest (9.0 mg) diazepam dose. Impairment of the information processing task by alcohol was midway between those produced by the large and medium diazepam doses. Since the comparison alcohol dose increases the probability of an accident by about 300%, the decrements associated with diazepam are socially significant, indicating that driving or operating machinery under the drug's influence could be dangerous to the user.

THE IMPACT OF MOTOR VEHICLE INDUCED TRAUMA ON HOSPITAL USEAGE (SIC): AN EXPLORATORY STUDY

Using a specially designed reporting form, hospitals in an eight-county area of Central Indiana (population of approximately 1,200,000) reported on randomly selected emergency room visits by category of injury: trauma (restricted to motor vehicle accidents), cardiac, burn, poison, neonatal, and behavioral. A census of all ambulance runs in the region was conducted during the same Fall 1978 period to determine the percentage of runs in response to a motor vehicle accident. When the percentage of motor vehicle trauma victims arriving by ambulance who were admitted to the hospital was calculated, it was found that motor vehicle trauma accounted for 648 cases or 44.4% of all reported cases, and of the 320 cases who arrived by ambulance, 87 or 27.6% were admitted to the hospital. Using an Indiana Hosp. Assoc. figure of 9.5 days as the mean stay for a motor vehicle trauma patient, it was calculated that in the Central Indiana region, motor vehicle trauma accounts for 68,591 bed days per year (3.6% of all region bed days).

PLANNING ROADSIDE SAFETY IMPROVEMENT PROGRAMS

Roadside analyses were made for 300 fixed-object crashes (and 300 comparison sites), selected from a population of property-damage-only, nonfatal-injury, and fatal crashes that occurred in three Georgia counties during a five-month period in 1977-1978. The results generally validate the findings of a similar 1974 roadside study in Georgia. Based on both studies, it is concluded that fixed-object crashes are more likely to occur for the following road conditions: along arterial and collector roads, along the right side of the road, along curved sections, along the outside of curves, in the area downstream from a curve, along a road with a negative gradient, and along a road with narrow pavement and shoulder. Approximately 90% of these crashes result from collisions with objects within 30 ft of the pavement edge. The general fixed-object accident site is best discriminated from a comparison site by a combination of curvature greater than 9 degrees and downhill gradient steeper than 3%; for the fatal fixed-object crash site, the corresponding figures are 6 degrees and 2%.

MOTORCYCLE ACCIDENT DATA--A VOID TO BE FILLED

In 1978, the American Automobile Assoc. and the Motorcycle Safety Foundation (MSF) surveyed 1475 local jurisdictions (representing a total population of 57,682,291) to obtain basic demographic data on 1977 motorcycle accidents; 88% of the localities responded. The MSF also surveyed the 50 states and the District of Columbia to determine the availability of motorcycle accident data on the state level; 36 states responded, representing a total population of 144,521,000. It was found that the most critical time period for motorcycle use is between 4 PM and 6 PM, followed by the very early morning hours; cyclists between 20 and 24 years old have the most accidents, followed by those 25 to 34 years old. Urban locations have more accidents than rural ones. Only 13 states (36%) could provide information on operator or passenger helmet use at the time of the accident. Accident report forms often fail to provide information on headlight use during daytime operation. There is a critical need for various types of exposure data: motorcycle mileage, motorcycle usage on various highway configurations, and sizes of motorcycle used. Tabulated and graphical information is appended.

CHILDREN KILLED IN CRASHES

A series of 89 deaths of children from 0 to 14 years of age in Maryland crashes during 1973-1977 were studied to illustrate problems of inadequate child restraints. Emphasis was on infant deaths, since little attention has been given to the especially high risk of death during the first six months of life. Of the 89 children who died, 87 were not properly restrained, one-fourth of these being ejected from the vehicle (indicating the inadequate design of doors and glass). Eight children were reported to have been traveling on their parents' laps. Of the nine infants less than six months old who were killed, three were in devices unsuitable for use in cars. Other sources of inadequate protection were improper securing of restraints, and traveling in the front seat. Beside proper use of acceptable child restraints, additional ways to reduce the likelihood of child injury include: reducing vehicle travel by children, driving at lower speeds, and using the larger of two family vehicles for transporting children. However, since there is little hope for changing parent and driver behavior to effect the child occupant safety, what is needed are greater use of mass transit, roadway modifications to automatically reduce crash frequency and devices that prevent or reduce injuries in crashes such as air bags, and impact-attenuators. Also needed are vehicle interior designs to prevent occupant ejection and to ensure that possible contact surfaces have a minimum potential for injury. Case reports and crash test photos are included.

VEHICLE DOWNSIZING AND ROADSIDE SAFETY HARDWARE

Reexamination of roadside safety hardware research is discussed in light of passenger car downsizing. Current roadside protection device designs and performance criteria are based mainly on experience with vehicles in the 2250 and 4500 lb weight range. An analysis of future vehicle downsizing trends suggests that vehicles as light as 1700 to 1800 lb need to be considered, since it is known that crash severity increases with decreasing vehicle weight in collisions with pole-like structures. High-speed, off-center impacts of small cars into such structures may result in violent multiple rollovers. Safety performance criteria for breakaway signs and luminaire supports, base-bending signs, and other poles/supports need to be reexamined. Vehicle geometry, inertial characteristics, and crash properties of mini-sized cars may present special problems in the design of traffic railings. Snagging of support posts and vehicle rollover have been observed in tests with these small cars. Impact attenuators also need to be reexamined. The Honda Civic has been selected as the initial mini-sized vehicle of interest in Federal Hwy. Administration-sponsored research. Current research includes minicar-bridge rail (current) crash testing, and analysis of minicar problems with shaped concrete median barriers. A planned study will investigate minicars and small sign supports.

OCCUPANT PROTECTION IN INTERIOR IMPACTS. AN ANALYSIS OF FEDERAL MOTOR VEHICLE SAFETY STANDARD NO. 201

The design of motor vehicle interior features likely to be impacted in frontal crashes (e.g. instrument panels, and front seat backs) are discussed according to the extent to which they are subject to Federal Motor Vehicle Safety Standard (FMVSS) 201. The need to design such interior compartment structures to reduce injuries is especially important for child safety. It is advocated that FMVSS 201 is inadequate, since it is based primarily on likely head impact areas of lap belted adult passengers, and applies only to parts of the top of the instrument panel ahead of center and right front passengers, to very limited parts of the top of the front seat backs without adjustable head restraints, or to the center point on the tops and backs of adjustable head restraints; and to sun visors, arm rests, and some interior storage compartment doors. Studies indicate that these areas are seldom impacted by occupants in crashes. The present standard is a much weakened version of the original standard (31 Jan 1967) which was intended to provide initial, minimum requirements for interior impact protection. The 1967 standard in turn was weaker than the 1966 proposal which included requirements for unrestrained child impact areas. An amended standard proposed in 1970, dealing comprehensively with interior impact protection, was never implemented. Many design features of current model cars increase injury potential (e.g. metal edges, rigid surfaces, hard protrusions, inadequate padding), but are not covered by FMVSS 201. Some automakers have emphasized injury reduction in interior design, illustrating the practicability, aesthetic appeal, and functional convenience of such designs. FMVSS 201 should be upgraded to require much less hazardous designs. Photographs of both potentially injurious interior design, and design features exceeding FMVSS 201 requirements are included.

A FUNDAMENTAL LOOK AT SIDE IMPACT

Side impact data are analyzed using a method based on th velocity-time histories of seven key points on the colliding vehicles (firewall and bumper of the impacting vehicle, and nea side of the impacted vehicle, side of door (with crash padding on opposite side from occupant, padded door facing occupant occupant, and far side of impacted vehicle). This method exhibits on a single graph the relationship among structural modifications, interior padding, intrusion, change-of-velocity of th struck car door, and human injury criteria. Using the model to analyze a side impact with a dummy and one matched collision using a cadaver, it appears that this method is compatible with current side impact injury levels. Areas on the velocity-time curves are shown to correspond to actual measured distances, slopes of curves to correspond to actual measured accelerations, and vertical lines to correspond to actual measured changes of velocities.

ANALYTICAL RECONSTRUCTION OF 12 STAGED COLLISIONS USING THE CRASH (CALSPAN RECONSTRUCTION OF ACCIDENT SPEEDS ON THE HIGHWAY) 2 AND SMAC (SIMULATION MODEL OF AUTOMOBILE COLLISION) PROGRAMS

To improve the utility of the CRASH (Calspan Reconstruction of Accident Speeds on the Highway) 2 and SMAC (Simulation Model of Automobile Collision) computer programs and to assess their limitations, 12 vehicle-to-vehicle collisions were staged and reconstructed using the programs. Results of the CRASH 2 program were judged on their degree of correspondence with the measured impact speeds and changes in velocity. The SMAC reconstructions were assessed on the basis of the accuracy of the predicted final rest positions, damage dimensions, and changes in velocity. In general, the reconstructions from both programs were acceptable. Recommendations to improve their utility include: for the CRASH program, to update the vehicle stiffness coefficients, particularly the rear-end impacts, and add a stationary vehicle option; for the SMAC program, to simulate hard points and corner effects and to provide an option to input cornering stiffness time history data in order to simulate weight transfer effects.

THE EFFECT ON INJURY AND FATALITY RATES DUE TO SEATBELT USAGE IN SASKATCHEWAN

In order to determine seat belt usage rates in Saskatchewan, Canada, five surveys were conducted between May 1977 and May 1979, at sampling stations across the province on urban streets, provincial highways, and municipal roads. Information was gathered on various driver, vehicle, restraint system, and trip characteristics. The first survey, which was conducted during an extensive publicity campaign, indicated overall usage was just under 20%. When legislation was passed on 1 Jul 1977, requiring all front seat occupants of motor vehicles to use the available safety restraints, usage rates in July had increased to over 50%. Motorists were given a three-month grace period to Oct 1 when enforcement of the law began. Although usage rates had increased to 73% in Oct 1977, by May 1978 they had decreased to just over 55%. Usage rates had leveled off to an average of 70% by May 1979. Cross-tabulations were made between usage and such variables as driver age, sex, education level, participation in driver education, frequency of seat belt use, and accident experience, as well as number of miles driven per year, roadway speed limits, and length of trip. Usage rates were higher for certain variables including: vehicles with seat belt buzzers; drivers in the 26- to 35-year-old age group, male drivers, drivers with high school or higher education level, high speed, and high-volume roadways. It was found that although total accidents and miles/driver/year have increased, injury and fatality rates have decreased since the enactment of the mandatory seat belt use law.

MOTORCYCLE RIDERS AND ALCOHOL--A PROBLEM?

A review is presented of the limited literature available on the subject of alcohol involvement in motorcycle crashes. Some data are presented from the Fatal Accident Reporting System on alcohol involvement in motorcycle operator fatalities (high percentage of questionable data); from a 1977 survey by the Motorcycle Safety Foundation (MSF) and the American Automobile Assoc. of communities throughout the U.S. concering operator blood alcohol concentration levels in fatal motorcycle accidents; and from the same type of survey by the MSF in 1977 of the 50 states. It is pointed out that the absence of uniform accident reporting systems throughout the U.S. has prevented clear definition of the motorcycle accident/alcohol relationship. Confusing the issue even further is a significant under-reporting of alcohol involvement in these accidents. From the information currently available, it can be said that alcohol is involved in from 3% to 6% of all motorcycle accidents, in 40% to 50% of all motorcycle fatalities in state studies, and in 21% to 28% of all motorcycle fatalities. Single-vehicle motorcycle accidents and fatalities show a higher percentage of alcohol involvement.

AN ALCOHOL, DRUG AND HIGHWAY SAFETY CONFERENCE IN MICHIGAN

A conference was held on 14-15 May, 1978, to provide a forum for information exchange and discussion of public policy regarding alcohol (and other drug) involvement in traffic accidents. The conference design included modifications of delphi technique and nominal group process techniques. Participants included doctors, judges, law enforcement personnel, driver improvement analysts and licensing specialists, educators, and safety council personnel. Discussions involved the identification of individuals who make up the alcohol-involved accident problem, and the traffic system's public policy-generated responses to the individual. It was concluded that most people do not seem to understand the mechanisms of impairment or their consequences, and that the traffic law system for dealing with the drug-abusing driver makes it difficult to force individuals into treatment/rehabilitation programs at an appropriate stage in their abuse problem. Recommendations to promote understanding about drug impairment centered on school pupils, traffic law system personnel, and medical patients; improvements were recommended in the traffic law system itself (fairness, justice, efficiency) and for public perception of the system.

A PRELIMINARY STUDY OF THE PERFORMANCE OF AFTERMARKET STEERING WHEELS IN FRONTAL IMPACTS

Data are presented from the examination of vehicles equipped with aftermarket steering wheels constructed of various materials, that were involved in frontal collisions. The injuries sustained by the drivers of these vehicles are examined, including those specifically caused by occupant contact with the aftermarket steering wheels. Some of the aftermarket steering wheels, such as those constructed of chain link, wrought iron, or hard plastic appear to pose a possible safety hazard to occupants who contact these objects in a collision, but others utilizing a token rubberized foam padding could afford occupants some protection. The wheels that appear to subject occupants to the most risk are those of a reduced size (8-10 in in diameter) and of extremely rigid nonyielding construction. Separation of the metal spokes from the rim has been seen in some instances and these protruding metal objects could also contribute to the injury causation of the occupants. Reduced diameter steering wheels could decrease the drivers ability to control and rapidly maneuver a vehicle. There is sufficient evidence to indicate that further study of the injury-producing effects of aftermarket steering wheels is needed. Handling tests should also be conducted to determine the effect of reduced diameter wheels on driver control and maneuverability. After-market steering wheels should conform to relevant Federal Motor Vehicle Safety Standards. It was also noted that most of the vehicles with aftermarket steering wheels had disconnected horns, thus eliminating a safety feature. Photographs are included.

REARWARD-FACING INFANT RESTRAINTS: OPTIMUM RECLINING ANGLES FOR THE DESIGN OF SAFER, MORE PROTECTIVE AND COMFORTABLE RESTRAINTS

A study was undertaken of rear-facing infant restraints to determine the optimum reclining angle that will provide adequate support for the infant at rest, and the optimum reclining angle that on impact will afford the best back, neck, and head support for the infant without imposing undue loading on the infant's shoulders. Rear-facing restraints were installed on an auto seat with a slope representative of the average seat slope in 1978 and 1979 cars. An infant was placed in each restraint which was then positioned at the manufacturer's recommended reclining angle(s), and the back and head support provided by each was evaluated. These restraints were then impact sled tested as installed on the average-sloped auto seat, and the harness loading on the shoulders of a six-month-old-child dummy was measured for each seat. In the comfort and support evaluation, the infant showed immediate, obvious discomfort in several more-upright restraints, the harness system in some restraints developed slack (resulting in bean bagging of infant's body), and it was indicated that incorrect positioning of an infant in a restraint could result in injury. There is not sufficient consistency in sled test results to draw even a tentative conclusion regarding a relationship between the degree of rotation of a restraint on impact and the total peak load on the shoulder harness. The results suggest that restraint rotation under impact (and dummy stress) increases as the back angle of the restraint becomes more upright. Photographs are included.

STATISTICAL MODELS FOR POLICY ANALYSIS (HIGHWAY SAFETY)

The use of statistical models for highway safety policy analysis is addressed, stressing the importance of interaction between managers and model analysts for developing and applying these models. An injury prediction model is described which has two phases: estimation of the expected Abbreviated Injury Score (AIS) for a vehicle occupant using a set of crash variables, and estimation of the severe injury rate and the fatality rate in towaway crash by using the expected AIS. Two examples illustrate the use of the crash injury prediction model to analyz questions asked by policy makers within the National Hwy Traffic Safety Administration. The first example involves the economic tradeoff between crash injury and fuel economy associated with vehicle weight reductions. Substantial savings from fuel economy are indicated, a portion of which could be used for incorporating additional occupant protection into vehicles. The second example examines the potential interaction between vehicle size and passive restraints. It is indicated that passive restraints are not likely to provide greater injury reduction in cars under 3600 lbs. Injury severity will be reduced more by passive restraints in large cars partly because occupants of these cars tend to be older people who are more susceptible to injury, although cars under 2200 lb are more favorably affected by passive restraints than are larger cars.

PRELIMINARY FINDINGS FROM THE NATIONAL CRASH SEVERITY STUDY

Preliminary results are summarized from the National Crash Severity Study (NCSS). The data was compiled over a two-year period (1977-1979) on 6216 passenger car crashes involving 13,525 occupants. At least one car in each accident was disabled. Only 8.4% of the vehicle occupants were wearing seat belts, compared to about 14% of the total population. Nearly one-third of all fatalities, and nearly one-fourth of all seriously injured occupants were ejected from the vehicle; more than half of the ejections occurred in rollover accidents. It was found that the likelihood of an occupant being seriously injured or killed in a side impact is about twice that for a frontal collision. Serious injuries and fatalities were found to generally correlate with higher speed crashes. Half of all the NCSS fatalities occurred in crashes in which the vehicle changed velocity by at least 35 mph. It was determined that some rear occupants, who are seated well away from the point at which an automobile is struck, and occupants who are properly restrained may be less seriously injured than would be indicated by vehicle damage. Some of the NCSS occupants survived crashes at more than 40 mph.

55 MPH FACT BOOK. 4TH ED.

Background information on the imposition of the fifty-five mile per hour speed limit and its safety benefits is followed by tabular data and graphs pertaining to the speed limit, including data, mainly covering the 1973-1978 period, on motor vehicle fatality rates (by state, per 100 million vehicle miles, by age group, by vehicle class, and for pedestrians); vehicle speeds (exceeding 55 and 65 mph, and average and 85th percentile speeds, by state);

highway travel (millions of vehicle miles, by state); average fuel economy ratios for 10 mph increments in speed for 1965-1970 and 1973-1977 model year cars; and annual arrests for noncompliance, by state. Graphs for each state indicate speed trends from 1977 to the first quarter of 1979. Appended are motor vehicle statistical data: total travel, 1950-1977; annual travel on main rural roads, 1966-1977; annual traffic on main rural roads as percentage of 1965; basic data on traffic accidents, 1957-1977; traffic fatalities, fatality rates, drivers, vehicles, and vehicle miles of travel (1961, 1966, 1974 to 1978). Also appended are the legislative background and authority of the 55 mph law, including PL 95-599, and a state-by-state summary of penalties for violation of the 55 mph speed limit.

ULTRASONIC INSPECTION OF TEN RETREADED TIRES AND THIRTY-TWO CASINGS. FINAL REPORT

Forty-two tires were subjected to nondestructive ultrasonic inspection. Of these, 10 were retreaded tires with measured belt edge separations of the tire shoulders; the remainder were 32 tire casings reported to be in good condition and ready for retreading. Ultrasonic data were analyzed and numerical scores from one (poor) to nine (excellent) were assigned tire tread, belts, sidewalls, and carcass. Tires were ranked in order of overall numerical scores. Of the 10 tires with belt edge separations, five had a belt score of 5 and four had a belt score of 7 or less. There was no unique correspondence between belt score and reported separation size, although three tires with low belt score (5) had reported separations of 5 or 7 mm, whereas only one tire with a higher belt score (6) had a separation of longer than 3 mm. Belt scores for the 32 casings were as follows: 3 for one casing; 4 for two casings; 5 for one casing; 6 for five casings; 7 for five casings; 8 for eight casings; and 9 for ten casings. Using the threshold score of 7 to separate defective casings from the remainder, 16 of the 32 tire casings were suspect.

NHTSA EVALUATION PLAN FOR FEDERAL MOTOR VEHICLE SAFETY STANDARD 208, OCCUPANT CRASH PROTECTION

The National Hwy. Traffic Safety Administration's (NHTSA) proposed plan for evaluating automatic restraint systems and Federal Motor Vehicle Safety Standard (FMVSS) 208 during the period 1980-1986 covers passenger cars equipped with automatic crash protection both prior to and after the standard's effective dates. The revised version of FMVSS 208 requires automatic crash protection for front seat occupants in full-sized automobiles beginning in model year 1982, in intermediate and compact cars in model year 1983, and in subcompacts in model year 1984. The evaluation is designed to measure the actual overall effectiveness of automatic restraints in reducing fatalities and injuries in highway crashes; to observe the operational characteristics of these restraints in actual use and their effectiveness in specific crash situations; to assess public acceptance and utilization of automatic restraints; to assess the industrial consequences of the standard; and to perform a cost analysis of the standard, including costs of manufacturing, repair, and replacement, as well as insurance savings. Background information is given on the evaluation plan for FMVSS 208, as well as the range of NHTSA activities related to implementation and enforcement of the standard and development of occupant protection systems. Thirty specific evaluation questions are examined in detail. A description is provided of each of 14 evaluation projects recommended for inclusion in the plan. The plan's four sections include prioritization of the 30 objectives, listing of projects (including completion milestones), a summary plan schedule for the projects, and a preliminary projection of resource requirements.

A MANUAL OF ANTI-THEFT GUIDELINES FOR STATE MOTOR VEHICLE TITLING PROGRAMS

This manual is intended to aid states in detecting stolen motor vehicles before they are "fenced" under the cloak of legitimate ownership documents. The vehicle theft problem and the relationship of the titling process to vehicle theft are summarized. Techniques common to commercial/professional vehicle theft operations for retitling stolen vehicles are described, including salvage switch, altered or stolen vehicle identification numbers, and fraudulent documents (counterfeit, altered, or stolen). Weaknesses in the generalized titling/registration process that are vulnerable to these techniques are identified for the areas of document intake and processing, vehicle processing for title/registration, and salvage vehicle and document processing. More general deficiencies that affect the overall titling/registration process are described related to document uniformity, title document security, and related laws. Policies and procedures are suggested for counteracting the procedural weaknesses. Appended are National Hwy. Traffic Safety Administration guidelines for state motor vehicle titling and anti-theft programs.

INTERNATIONAL TECHNICAL CONFERENCE (7TH) ON EXPERIMENTAL SAFETY VEHICLES, PARIS, JUNE 5-8, 1979

Following opening remarks and professional data on recipients of awards for contributions to automotive safety, status reports are presented on motor vehicle safety, by government and industry representatives from U.S., Japan, Italy, Federal Republic of Germany, U.K., and France, as well as special guest speaker presentations, and a panel discussion on the experimental safety vehicle program. Papers follow from six technical seminars: frontal crash protection and passive restraint development; biomechanics and dummy development; side impact protection; accident investigation and data analysis; pedestrian protection; and braking, handling, and stability. A panel discussion on rulemaking intentions of the U.S., European, and Japanese governments, and closing remarks are reported. Included is a list of participants grouped by country and subgrouped by affiliation, or under other categories (international organizations, press).

PASSENGER CAR/PEDESTRIAN IMPACT PROTECTION SYSTEM EVALUATION. FINAL REPORT

The application of pedestrian protective front-end designs was studied using four candidate vehicles representing the 1979 passenger car fleet, the Dodge Omni, Ford Fairmont, Chevrolet Malibu, and Chevrolet Impala. The focus of the study was to analyze the cost and weight changes for a passenger car/pedestrian initial impact protection system, based on an engineering assessment using existing data. A protective system which did not meet Part 581 Standard requirements was compared to a system which met those requirements. When propagated weight changes (based on a 1.75 factor or a 1.5 factor) are considered for the pedestrian impact protective design not meeting the Part 581 Standard, the maximum weight increase per vehicle would be on the Dodge Omni and the greatest weight saving would be on the Chevrolet Impala. The total vehicle cost changes including that of the propagated weight based on a 1.75 factor range from an increase of $55.80 on the Ford Fairmont to $17.20 on the Chevrolet Impala. Based on a 1.5 factor, the cost range would be from an increase of $55.58 for a Ford Fairmont to an increase of $20.04 for a Chevrolet Impala. When the same propagated weight changes are considered for the pedestrian impact protective design that meets the Part 581 Standard, the maximum weight increase per vehicle would be on the Dodge Omni and the greatest weight saving would be on the Chevrolet Impala. The total vehicle cost changes including that of the propagated weight based on a 1.75 factor range from an increase of $76.69 on the Ford Fairmont to $40.99 on the Chevrolet Malibu. Based on a 1.5 factor, the cost range would be from an increase of $75.51 for a Ford Fairmont to an increase of $42.08 for a Chevrolet Malibu. A total leadtime of three model years would probably be required by the industry to meet a new Standard. A total industry investment of about $30 million would be required to provide the equipment and facilities for the front end system production.

A PLAN FOR REGIONAL COOPERATION: PUBLIC INFORMATION AND EDUCATION FOR HIGHWAY SAFETY INCLUDING COMMUNICATIONS PLANS AND STRATEGIES. FINAL REPORT

A cooperative approach among states in Dept. of Transportation Region VIII (Colorado, Montana, Wyoming, South Dakota, North Dakota, and Utah) was investigated for conducting public information and education (PI and E) campaigns on occupant restraints. The concept of regional cooperation is discussed, and present occupant restraint programs in Region VIII states are briefly described. Although certain differences of opinion exist among the states concerning the efficiency of seat belt campaigns, there is general agreement that coordination of research and identification of critical markets are worthy of a regional cooperative approach. A framework for regional cooperation in PI and E is presented which addresses the issues of management, funding, and distribution of materials produced. The dominant theme of this recommended program is "Share the Risks and Share the Benefits." Appended are a two-year planning cycle for a safety campaign; a sample request for proposal (contractor support); and suggestions regarding a seat belt PI and E campaign, questions for group discussions or individual interviews concerning seat belts, and a series of campaigns aimed at intermediaries (e.g. police, parents, media). Attached are a National Hwy. Traffic Safety Administration memorandum concerning the pooling of 402 funds, and suggested procedures for joint-funding administration.

EVALUATION OF THE FEASIBILITY OF A SINGLE-BEAM HEADLIGHTING SYSTEM. FINAL REPORT

A study was undertaken to develop an improved headlamp beam for use in conditions of oncoming or preceding traffic. After a review of the literature concerning headlighting and visual perception and consultations with lighting industry representatives, a number of candidate beam patterns were evaluated by two computer models. One model estimates the visibility distance provided to various areas under a variety of road conditions, while the other produces a "figure of merit" for each beam (i.e. percentage of time it simultaneously meets certain visibility and glare criteria). Based on this evaluation, three different beam patterns were selected for field testing (a similar pattern to the SAE low beam but with upgraded intensity, a beam with more light to the right of the road, and a beam with more light to the left of the road). Results of subjective and objective tests indicate that the best of the test lamps (upgraded SAE low beam) was only marginally better than the standard SAE low beam. The implication is that overall improvements in low-beam headlighting will not come easily.

PERFORMANCE CHARACTERISTICS OF 1977 FORD 300 CID (CUBIC INCH DISPLACEMENT) ENGINE. FINAL REPORT

Experimental data were obtained in dynamometer tests of a 6-cylinder spark ignition 1977 Ford 300 cu-in-displacement engine with a catalytic converter, exhaust gas recirculation, manifold preheated air inlet system, alternator (driven only, no output), and fan. The engine as equipped is intended for use in a 49-state (Federal) vehicle with automatic transmission. The testing was designed to obtain engine performance data for estimating fuel consumption and emissions (carbon monoxide, hydrocarbons, and nitrogen oxides) for varied engine service and duty, and to provide basic engine characteristic data required for the Transportation Systems Center Vehicle Simulator computer program. A test report and discussion of results are followed by tabular and graphical summaries of engine map data.

RESULTS OF ENERGY-LOSS MEASUREMENTS ON PASSENGER CAR TIRES OPERATING IN THE FREE-ROLLING AND BRAKING/TRACTION MODES. FINAL REPORT

Energy-loss measurements were made on 12 passenger car tires under three different test conditions: with the tire in a straight, free-rolling condition; subjected to driving/braking torques based on the Federal Urban Driving Cycle (LA-4); and subjected to driving/braking torques based on the Federal Highway Fuel Economy Test (HFET). The tire sample, representative of current original equipment, ranged in size from a P155/80D13 to an HR78-15. It was found that energy-loss values for a given tire are, in general, the smallest for steady-state, free-rolling test conditions and the largest for LA-4 traction conditions. Relative ranking among tires with respect to energy-loss level appears to be relatively independent of the type of test cycle employed. Energy-loss levels measured under conditions of driving/braking traction are very sensitive to the magnitude and duration of the time rate of change of the applied wheel torque. Recommendations are made for future testing. A tabular summary of the LA-4 and HFET volocity-torque schedules, the General Motors tire performance criteria break-in procedure, and a description of Calspan's Tire Research Facility are appended.

AN ASSESSMENT OF STATE AND COMMUNITY HIGHWAY SAFETY PROGRAMS, FY 1975-FY 1979

Section 402 State and Community Highway Safety Grants Program costs and benefits are analyzed for fiscal years 1975-1979, with emphasis on the nine program areas which utilize 90%-95% of 402 funds. These program areas include planning and administration, driver education, driver licensing, alcohol safety, traffic records, emergency medical services (EMS), pedestrian safety, police traffic services, and school bus safety. Special attention is also given to those areas for which Congress authorized High Payoff Funds: control of the drinking driver, speed limit enforcement, EMS, and other areas aimed directly at reducing accident fatalities and injuries. It is concluded that the 402 program has made important contributions in reducing accidents, preventing fatalities and injuries, upgrading highway safety support systems, and that the program has made most modern highway safety practices available to all levels of state and local governments. These accomplishments have been made in spite of 1970's inflation, competing program requirements, and limited resources at all government levels.

MARIJUANA, OTHER DRUGS AND THEIR RELATION TO HIGHWAY SAFETY. A REPORT TO CONGRESS

Efforts are reported to detect and prevent marijuana and other drug use by motor vehicle operators. Similarities and differences between alcohol and drugs as related to highway safety are discussed, as are the frequency of drug use among drivers and its effect on highway safety, the legal approaches to the control of drug use by drivers, and Federal and state activity in detection and prevention of inappropriate drug use by drivers. Although methods of detecting drug presence in blood have improved over the past decade, detection of most drugs, including marijuana, in breath or saliva, is not possible now or in the near future. Only ten states have effective combinations of drug-and-driving laws. State traffic laws impeding effective law enforcement, and lack of data relating specific drug levels to driving impairment, limit the ability of law enforcement agencies to detect and prevent use of drugs by drivers. Although a series of studies is being sponsored by Federal agencies investigating drug effects, and some states have begun programs to collect pertinent data, much time and research will be required for a complete understanding of the problem. Except for alcohol, no drug has been established as a high priority highway safety concern. The frequency with which drug-impaired drivers drive, are arrested, or are involved in crashes is not known. Drugs which may impair driving include prescription and over-the-counter drugs as well as illicit drugs. Information on marijuana and driving is incomplete, and does not support arguments either for or against marijuana as a high priority highway safety concern. Extensive roadside surveys are needed to determine the nature and extent of drug use by drivers who are not involved in accidents or suspected of impaired driving. Revision of existing state laws is recommended to permit appropriate law enforcement, especially governing the use of chemical tests and definitions of driving under the influence of alcohol and/or drugs. An information and education program and continued research are recommended. The National Academy of Sciences will be requested to consider the feasibility of developing reliable chemical tests for drugs and of identifying drug concentration levels as valid indicators of driving impairment, as well as examining the use of the criminal law system as the primary countermeasure approach to the problem.

HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION: CONFERENCE PROCEEDINGS. FINAL REPORT

The 1979 Conference on Hwy. Safety Res., Devel., and Demonstration was held to review proposed activities to be undertaken by the National Hwy. Traffic Safety Administration over a five-year period, FY1980-FY1984. Program plans and recommendations reviewed include 55 mph noncompliance and other unsafe driving acts; occupant restraints; alcohol and drugs; pedestrian, bicyclist, and student transportation safety; driver licensing; motorcycle and moped safety; young drivers; Emergency Medical Services; state traffic records; state program management; traffic law adjudication; police traffic services; motor vehicle registration, titling, and antitheft; and the National Driver Register. In addition to specific program elements, issues are reviewed related to program priorities, the basis for their selection, the transfer of program results, and their responsiveness to the needs of the national highway safety community. More than 200 conference participants are listed with their affiliations.

AIR BAG INFLATOR RELIABILITY

Air bag inflators used in production automobiles will be among the most reliable components in a car. The companies making them--Thiokol Chemical Corp., Talley Industries, and Rocket Research--have extensive aerospace experience and are aware of the need for exceptionally reliable performance. A typical air bag system is described, including the function of an inflator. The experience of more than 10,000 GM production cars on the road with air bags is outlined. The malfunctions of experimental "workhorse" inflators are not indicative of the reliability of production airbag systems because of differences in design and use. A comparison of the reliability of production air bag systems with that of other safety components in automobiles shows the air bags to be far more effective than seat belts, and more reliable than other auto safety components such as brakes, tires, and lights. The 10,281 GM cars with air bags sold from 1974-1976, in more than 600 million miles, recorded 189 deployment crashes with 378 air bags deployed, and experienced no fires, hot gas leaks or other inflator malfunctions, and no failure to deploy, for an estimated reliability of more than 99%.

FINAL IMPACT ASSESSMENT OF THE LIGHT TRUCK AND VAN FUEL ECONOMY STANDARDS FOR MODEL YEARS 1980 AND 1981

The impacts of the proposed fuel economy standards for mode years 1980 and 1981 light trucks and vans are analyzed, ove and above the standards set for model year 1979, and a level i assumed for vehicles not subject to the 1979 standard. Th assumptions used in this analysis are explained. A micro-assessment is given of the proposal's impact on individual manufacturers and consumers, followed by a macro-assessment of impact on energy consumption, employment, and the national economy. The various alternatives considered by the NHTSA in its final rulemaking are also discussed, including different levels of fuel economy, the inclusion or exclusion of captive imports, and alternatives in vehicle classification. A discussion of cost estimates is appended.

LIGHT TRUCK FUEL ECONOMY STANDARDS. MODEL YEAR 1981. RULEMAKING SUPPORT PAPER

Development of final fuel economy standards is described for pickups, vans and utility vehicles manufactured during model year (MY) 1981. These standards include an amendment to the MY 1981 fuel economy standards for 2-wheel vehicles issued in Mar 1978, and evolve from the Notice of Proposed Rulemaking (NPRM) issued in Dec 1978. The standards have been developed from information used in the Mar 1978 rulemaking, information supplied by the Chrysler Corp. and the other light truck manufacturers in response to a Jul 1978 questionnaire on light trucks, and subsequent Chrysler responses to agency inquiries, as well as information supplied by manufacturers of light trucks, by lubricant suppliers, and by other interested parties. Following a comparison of the 1977 and 1979 baselines, technology improvements are considered (engine improvements, alternative engines and turbochargers, transmissions, improved accessories, lubricants, rolling resistance, aerodynamic improvements, weight reduction, and reduction in engine size and axle ratio), with the current manufacturers' estimates of their capability and the agency's final position. Alternatives, imports and captive imports are discussed. The agency's decision in the determination of 1981 light truck fuel economy standards is explained. The impact of the action on the economy and the environment is considered, and a docket summary includes comments by automobile manufacturers, suppliers, businesses, citizen groups, trade associations, and private citizens.

LIGHT TRUCK AND VAN FUEL ECONOMY STANDARDS FOR MODEL YEARS 1980 AND 1981. RULEMAKING SUPPORT PAPER SUPPLEMENT

The development of final fuel economy standards for light trucks, vans, and utility vehicles for model years (MY) 1980 and 1981 is described. The standards apply to all light trucks (LT's) of 8500 lb gross vehicle weight rating and less with a curb weight of 6000 lb or less and a frontal area of 46 sq ft or less. Classification by number of driving wheels is proposed. The fuel economy requirements are 16.0 mpg in MY 1980 and 18.0 in MY 1981 for 4x2 LT's; 14.0 mpg in MY 1980 and 15.5 mpg in MY 1981 for 4x4 LT's; and 14.0 mpg in MY 1980 and 15.0 mpg in MY 1981 for LT's from manufacturers whose fleet of LT's uses basic engines that are not also used in passenger automobiles. Captive imports must meet the same fleet average requirements as for other 4x2 and 4x4 LT's. Background information on the standards is followed by discussions of technology improvements, alternative fuel economy levels and determination of maximum feasible fuel economy, economic impact and fuel savings, and impact on the environment. A docket summary outlines comments received by the National Hwy. Traffic Safety Administration on the rulemaking. Appended are results of a study of electronic engine control for improved fuel economy.

POLICE TRAFFIC RADAR: IS IT RELIABLE?

Technical innovations in police traffic radar, especially the development of "moving radar," have caused the public and the courts to question the reliability and accuracy of modern traffic radar devices and the adequacy of police radar operator training. The National Hwy. Traffic Safety Administration has entered into an interagency agreement (DOT-HS-7-01697) with the National Bureau of Standards (NBS) to develop performance standards for police speed measuring devices, and is developing a model training program in use of these devices. Information is presented on a series of laboratory and field tests conducted by the NBS on police traffic radar equipment questioned in a Judicial Hearing in Dade County, Fla. The NBS researchers were especially concerned with the susceptibility of the radar devices to interference from Citizens Band and police radios, and police cars' ignition, alternator, and air-conditioner and heater fans. They also examined problems such as patrol speed shadowing, target speed bumping or batching, and possible errors due to panning, scanning, interpreting the cosine angle effect, and the automatic lock-on feature. It was concluded, from tests of the six devices identified in the Dade County hearing, that radar is a reliable tool when properly installed and operated by skilled and knowledgeable operators. It is recommended that uniform statewide standards, guidelines and procedures be established for: operator training and certification; equipment purchase, maintenance, testing and certification; operating practices; and periodic recertification of both equipment and operators.

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. PARTICIPANT'S MANUAL

A manual is provided for the participant in a seminar directed toward increasing pre-sentence investigation (PSI) personnel's awareness of the necessity for, and importance of, identification of the level of alcohol abuse among the DWI (driving while intoxicated) offender population. The seminar focuses on an explanation of the Alcohol Safety Action Proj.'s health/legal approach to the DWI problem, particularly on screening procedures. The manual contains the seminar agenda, and information on each of the nine seminar units (introduction and overview, the problem drinking driver, alcohol and impairment, the responsibilities of PSI personnel, screening instruments, practical application, report writing, court-monitored rehabilitation programs, and summary). Appended are facts on alcohol use and abuse, and sample tests.

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. INSTRUCTOR'S GUIDE

An instructor's guide is provided for a seminar directed toward increasing pre-sentence investigation (PSI) personnel's awareness of the necessity for, and importance of, identification of the level of alcohol abuse among the DWI (driving while intoxicated) offender population. The seminar focuses on an explanation of the Alcohol Safety Action Proj.'s (ASAP) health/legal approach to the DWI problem, particularly on screening procedures. The guide provides an overview of the seminar, followed by guidelines for conducting each of nine units: introduction and overview, the problem drinking driver, alcohol and impairment, the responsibilities of PSI personnel, screening instruments, practical application, report writing, court-monitored rehabilitation programs, and summary. The guidelines for each unit consist of two parts: a summary page, indicating instructional methods and objectives, and references to be used; and the actual lesson plan. Appended are facts on alcohol abuse, and sample tests. The two-day seminar can be conducted by one person, assuming that his knowledge and capabilities cover all necessary areas, and he has access to local background information. The seminar is directed to persons with a 12th grade education (or higher), at least six months' experience as a court employee (paralegal or probation officer) or community agency employee, and high motivation to provide referral recommendations to the courts in DWI cases. Recommended class size is 12 to 15 persons. Two types of evaluation are used: pre- and post-seminar questionnaires, which measure the amount of new information gained by the participants; and a materials evaluation form, which assesses the participants' general impression of the training.

HIGHWAY TRAFFIC SAFETY SELF-INSTRUCTION COURSE. MODULE 8 WORKBOOK. ADMINISTRATIVE EVALUATION. 1ST ED.

A cassett tape/workbook training module concerning the administrative evaluation of State Highway Safety Programs is provided. This module was designed to provide new personnel, hired by a State Highway Safety Office, with an introduction to the magnitude of the highway safety program. The module will be of value to long-term employees as well, and to all persons concerned with highway safety within the U.S. The seven sections of this self-instruction module are as follows: introduction, concepts and purposes of administrative evaluation, administrative evaluation planning, administrative evaluation reporting, summary of module, glossary and appendices (Title 23, U.S. Code, Section 402; guidelines for writing objectives).

HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION: CONFERENCE PROCEEDINGS. FINAL REPORT
HS-805 231

DESCRIBING

VEHICLE CHARACTERISTICS DESCRIBING THE STEERING CONTROL QUALITY OF CARS
HS-028 453

DESIGN

A MANUAL FOR DESIGN AND CONSTRUCTION OF BICYCLE PATH PAVEMENTS. FINAL REPORT
HS-027 409

A NEW DESIGN FOR A SURROGATE SPINE
HS-028 419

AN OPTIMUM VISIBILITY DESIGN FOR THE STOP LAMP (BRAKE LIGHT)
HS-028 457

CAR DESIGN FOR PEDESTRIAN INJURY MINIMIZATION
HS-028 436

DESIGN AND DEVELOPMENT OF AN INDEPENDENT REAR SUSPENSION FOR THE 1979 CADILLAC ELDORADO
HS-027 359

DESIGN OF STEERING COLUMNS FOR PASSIVE RESTRAINT APPLICATION
HS-028 410

DESIGN SYNTHESIS OF A VEHICLE SUSPENSION SYSTEM USING MULTI-PARAMETER OPTIMIZATION
HS-027 390

MARKET-RELATED PASSENGER CAR DESIGN TO IMPROVE COLLISION PROTECTION FOR "OWN" VEHICLE AND "OTHER" VEHICLE
HS-028 400

REARWARD-FACING INFANT RESTRAINTS: OPTIMUM RECLINING ANGLES FOR THE DESIGN OF SAFER, MORE PROTECTIVE AND COMFORTABLE RESTRAINTS
HS-028 500

THE NATIONAL CRASH SEVERITY STUDY AND ITS RELATIONSHIPS TO ESV (EXPERIMENTAL SAFETY VEHICLE) DESIGN CRITERIA
HS-028 429

VEHICLE DESIGN FOR PEDESTRIAN PROTECTION
HS-028 442

DETECTORS
A STANDARD FOR VEHICLE DETECTORS. TENTATIVE REVISED STANDARD
HS-027 392

DEVICE
A PROTOTYPE LOAD-SENSING DUMMY FACEFORM TEST DEVICE FOR FACIAL INJURY HAZARD ASSESSMENT
HS-028 468

DEVICES
EFFECTS OF PEDIATRIC EDUCATION ON THE USE OF CHILD RESTRAINT DEVICES IN NORTH CAROLINA
HS-028 471

EXPERIMENTAL APPLICATION OF ADVANCED THORACIC INSTRUMENTATION TECHNIQUES TO ANTHROPOMORPHIC TEST DEVICES
HS-028 418

DIAGONAL
THE INFLATABLE DIAGONAL BELT (IMPROVEMENT OF PROTECTION IN THE CASE OF FRONTAL IMPACT)
HS-028 408

DIAZEPAM
THE EFFECT OF A SINGLE ACUTE DOSE OF DIAZEPAM ON DRIVING-RELATED SKILLS PERFORMANCE
HS-028 487

DIMENSIONAL
A ONE-DIMENSIONAL COMBUSTION MODEL FOR A DUAL CHAMBER STRATIFIED CHARGE SPARK IGNITION ENGINE
HS-027 355

OCCUPANT RESTRAINT SYSTEM MODELING USING THE MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL OCCUPANT DYNAMICS MODEL
HS-028 475

DIRECTION
STRONGER FEDERAL DIRECTION NEEDED TO PROMOTE BETTER USE OF PRESENT URBAN TRANSPORTATION SYSTEMS. REPORT TO THE CONGRESS
HS-027 388

DISCREPANCIES
THE DEGREE OF BENEFIT OF BELTS IN REDUCING INJURY--AN ATTEMPT TO EXPLAIN STUDY DISCREPANCIES
HS-027 406

DISPERSION
DISPERSION OF CARBON MONOXIDE FROM ROADWAYS AT LOW WIND SPEEDS
HS-027 338

DISPLACEMENT
PERFORMANCE CHARACTERISTICS OF 1977 FORD 300 CID (CUBIC INCH DISPLACEMENT) ENGINE. FINAL REPORT
HS-805 220

DOCUMENT
PROJECT PLANNING DOCUMENT. HIGHWAY VEHICLE ALTERNATIVE FUELS UTILIZATION PROGRAM (AFUP)
HS-027 372

DOSE
THE EFFECT OF A SINGLE ACUTE DOSE OF DIAZEPAM ON DRIVING-RELATED SKILLS PERFORMANCE
HS-028 487

DOWNSIZING
VEHICLE DOWNSIZING AND ROADSIDE SAFETY HARDWARE
HS-028 492

DRAG
SLASHING AERODYNAMIC DRAG: HOW COMPUTERS REDESIGN A CAR FOR MORE MPG
HS-027 341

DRINKING
COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. PARTICIPANT'S MANUAL

PROFILES OF FATAL COLLISIONS INVOLVING CHILD PEDESTRIANS
HS-028 466

FATALITY
THE EFFECT ON INJURY AND FATALITY RATES DUE TO SEATBELT USAGE IN SASKATCHEWAN
HS-028 496

FEASIBILITY
EVALUATION OF THE FEASIBILITY OF A SINGLE-BEAM HEADLIGHTING SYSTEM. FINAL REPORT
HS-805 219

MOTORCYCLE RIDER COURSE FEASIBILITY STUDY
HS-028 486

FEDERAL
NHTSA EVALUATION PLAN FOR FEDERAL MOTOR VEHICLE SAFETY STANDARD 208, OCCUPANT CRASH PROTECTION
HS-805 066

OCCUPANT PROTECTION IN INTERIOR IMPACTS. AN ANALYSIS OF FEDERAL MOTOR VEHICLE SAFETY STANDARD NO. 201
HS-028 493

STRONGER FEDERAL DIRECTION NEEDED TO PROMOTE BETTER USE OF PRESENT URBAN TRANSPORTATION SYSTEMS. REPORT TO THE CONGRESS
HS-027 388

FERROGRAPHIC
FERROGRAPHIC ANALYSIS FOR HYDRAULIC FLUIDS
HS-027 384

FILLED
MOTORCYCLE ACCIDENT DATA--A VOID TO BE FILLED
HS-028 490

FITTING
FITTING AND WEARING OF SEAT BELTS IN AUSTRALIA. THE HISTORY OF A SUCCESSFUL COUNTERMEASURE
HS-027 395

FLOWS
NUMERICAL PREDICTION OF AXISYMMETRIC LAMINAR AND TURBULENT FLOWS IN MOTORED, RECIPROCATING INTERNAL COMBUSTION ENGINES
HS-027 356

FLUID
STATUS REPORT ON SAE (SOCIETY OF AUTOMOTIVE ENGINEERS) RECOMMENDED PRACTICE J1227--"ASSESSING CLEANLINESS OF HYDRAULIC FLUID POWER COMPONENTS AND SYSTEMS"
HS-027 380

FLUIDS
FERROGRAPHIC ANALYSIS FOR HYDRAULIC FLUIDS
HS-027 384

FORD
PERFORMANCE CHARACTERISTICS OF 1977 FORD 300 CID (CUBIC INCH DISPLACEMENT) ENGINE. FINAL REPORT
HS-805 220

TURBOCHARGING FORD'S 2.3 LITER SPARK IGNITION ENGINE
HS-027 353

FORKLIFTS
FORKLIFTS: TINY TRUCKS, BIG HAZARDS
HS-027 386

FRANCISCO
SUBSIDIZED TAXI PROGRAMS FOR ELDERLY AND HANDICAPPED PERSONS IN THE SAN FRANCISCO BAY AREA. FINAL REPORT
HS-027 411

FREE
RESULTS OF ENERGY-LOSS MEASUREMENTS ON PASSENGER CAR TIRES OPERATING IN THE FREE-ROLLING AND BRAKING/TRACTION MODES. FINAL REPORT
HS-805 224

FRONT
IMPROVEMENT OF REAR AND FRONT LIGHTING SYSTEMS FOR MOTOR VEHICLES
HS-028 456

THE V-SHAPED VEHICLE FRONT--ITS INFLUENCE ON INJURY SEVERITY IN PEDESTRIAN ACCIDENTS AND SIDE COLLISIONS
HS-028 427

FRONTAL

A PRELIMINARY STUDY OF THE PERFORMANCE OF AFTERMARKET STEERING WHEELS IN FRONTAL IMPACTS HS-028 499

IMPROVED TEST PROCEDURES FOR FRONTAL IMPACT HS-028 403

OCCUPANT PROTECTION IN FRONTAL IMPACTS HS-028 409

PRESENTATION OF A FRONTAL IMPACT AND SIDE IMPACT DUMMY, DEFINED FROM HUMAN DATA AND REALIZED FROM A "PART 572" BASIS HS-028 417

RESULTS OF COMPARATIVE FRONTAL CRASH TESTS HS-028 404

THE INFLATABLE DIAGONAL BELT (IMPROVEMENT OF PROTECTION IN THE CASE OF FRONTAL IMPACT) HS-028 408

UPGRADED FRONTAL CRASH PROTECTION FOR MOTOR VEHICLE OCCUPANTS HS-028 405

FUEL

FACTORS INFLUENCING AUTOMOTIVE FUEL DEMAND HS-027 374

FINAL IMPACT ASSESSMENT OF THE LIGHT TRUCK AND VAN FUEL ECONOMY STANDARDS FOR MODEL YEARS 1980 AND 1981 HS-805 258

FUEL ECONOMY MODELS (FUEL AND FUEL6) HS-027 373

IMPROVEMENT OF CITYBUS FUEL ECONOMY USING A HYDRAULIC HYBRID PROPULSION SYSTEM--A THEORETICAL AND EXPERIMENTAL STUDY HS-027 347

LIGHT TRUCK AND VAN FUEL ECONOMY STANDARDS FOR MODEL YEARS 1980 AND 1981. RULEMAKING SUPPORT PAPER SUPPLEMENT HS-805 260

LIGHT TRUCK FUEL ECONOMY STANDARDS. MODEL YEAR 1981. RULEMAKING SUPPORT PAPER HS-805 259

THE EFFECT OF AMBIENT TEMPERATURE VARIATION ON EMISSIONS AND FUEL ECONOMY--AN INTERIM REPORT HS-027 401

FUELS

A COMPARISON OF PROJECTED ELECTRIC UTILITY PEAKING GAS TURBINE ENERGY REQUIREMENTS TO POTENTIAL ALCOHOL FUELS AVAILABILITY: 1980-2000 HS-027 371

PROJECT PLANNING DOCUMENT. HIGHWAY VEHICLE ALTERNATIVE FUELS UTILIZATION PROGRAM (AFUP) HS-027 372

FUNCTION

DEFINITION OF THE VEHICLE DYNAMIC CHARACTERISTICS BY THE TRANSFER FUNCTION: CORRELATION WITH SUBJECTIVE EVALUATION HS-028 454

PREDICTION OF THORACIC INJURIES AS A FUNCTION OF OCCUPANT KINEMATICS HS-028 413

FUNCTIONS

RADAR-CONTROLLED FUNCTIONS IN THE U.S. RESEARCH SAFETY VEHICLE (RSV) HS-028 450

FUNDAMENTAL

A FUNDAMENTAL LOOK AT SIDE IMPACT HS-028 494

GALLONS

RAMP METERING HELPS SAVE 4.5 MILLION GALLONS OF GAS HS-027 343

GAS

A COMPARISON OF PROJECTED ELECTRIC UTILITY PEAKING GAS TURBINE ENERGY REQUIREMENTS TO POTENTIAL ALCOHOL FUELS AVAILABILITY: 1980-2000 HS-027 371

EXPERIMENTAL ANALYSIS ON EXHAUST GAS TEMPERATURE OF VARIOUS FOUR CYCLE GASOLINE ENGINES HS-027 350

PREDICTION OF GAS EXCHANGE PROCESSES IN A SINGLE CYLINDER INTERNAL COMBUSTION ENGINE HS-027 357

RAMP METERING HELPS SAVE 4.5 MILLION GALLONS OF GAS HS-027 343

GASOLINE

EXPERIMENTAL ANALYSIS ON EXHAUST GAS TEMPERATURE OF VARIOUS FOUR CYCLE GASOLINE ENGINES HS-027 350

GUIDE

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. INSTRUCTOR'S GUIDE HS-900 035

GUIDELINES

A MANUAL OF ANTI-THEFT GUIDELINES FOR STATE MOTOR VEHICLE TITLING PROGRAMS HS-805 198

HANDICAPPED

SUBSIDIZED TAXI PROGRAMS FOR ELDERLY AND HANDICAPPED PERSONS IN THE SAN FRANCISCO BAY AREA. FINAL REPORT HS-027 411

TRANSPORT FOR THE ELDERLY AND THE HANDICAPPED--AN OVERVIEW FROM THE LATE 70'S HS-027 396

HANDLING

VEHICLE SAFETY CAR HANDLING AND BRAKING: LEGISLATION CAN NOT COVER EVERYTHING HS-028 459

HARDWARE

VEHICLE DOWNSIZING AND ROADSIDE SAFETY HARDWARE
HS-028 492

HAZARD

A PROTOTYPE LOAD-SENSING DUMMY FACEFORM TEST DEVICE FOR FACIAL INJURY HAZARD ASSESSMENT
HS-028 468

HAZARDS

FORKLIFTS: TINY TRUCKS, BIG HAZARDS
HS-027 386

HEAD

IMPROVED PEDESTRIAN PROTECTION BY REDUCING THE SEVERITY OF HEAD IMPACT ONTO THE BONNET (HOOD)
HS-028 440

HEADLIGHTING

EVALUATION OF THE FEASIBILITY OF A SINGLE-BEAM HEADLIGHTING SYSTEM. FINAL REPORT
HS-805 219

HEAT

HEAT TRANSFER IN THE STRAIGHT SECTION OF AN EXHAUST PORT OF A SPARK IGNITION ENGINE
HS-027 351

HELPS

RAMP METERING HELPS SAVE 4.5 MILLION GALLONS OF GAS
HS-027 343

HIGHWAY

A PLAN FOR REGIONAL COOPERATION: PUBLIC INFORMATION AND EDUCATION FOR HIGHWAY SAFETY INCLUDING COMMUNICATIONS PLANS AND STRATEGIES. FINAL REPORT
HS-805 217

ALCOHOL AND HIGHWAY SAFETY 1978. A REVIEW OF THE STATE OF KNOWLEDGE. SUMMARY VOLUME
HS-805 172

AN ALCOHOL, DRUG AND HIGHWAY SAFETY CONFERENCE IN MICHIGAN
HS-028 498

AN ASSESSMENT OF STATE AND COMMUNITY HIGHWAY SAFETY PROGRAMS, FY 1975-FY 1979
HS-805 228

ANALYTICAL RECONSTRUCTION OF 12 STAGED COLLISIONS USING THE CRASH (CALSPAN RECONSTRUCTION OF ACCIDENT SPEEDS ON THE HIGHWAY) 2 AND SMAC (SIMULATION MODEL OF AUTOMOBILE COLLISION) PROGRAMS

IMPROVING THE STABILITY OF A COMMERCIAL VEHICLE WHEN BRAKED
HS-028 447

POSSIBILITIES FOR IMPROVING SAFETY WITHIN THE DRIVER-VEHICLE-ENVIRONMENT CONTROL LOOP
HS-028 451

INACCURACIES

THE INACCURACIES OF POLICE RADAR: OVERDRIVE'S REPORT
HS-027 400

INATTENTION

INDICATORS OF DRIVER INATTENTION
HS-028 472

INCH

PERFORMANCE CHARACTERISTICS OF 1977 FORD 300 CID (CUBIC INCH DISPLACEMENT) ENGINE. FINAL REPORT
HS-805 220

INCORPORATED

A SAFETY SEAT WITH INCORPORATED BELTS. STUDY
HS-028 398

INCREASE

IS FURTHER LEGISLATION REQUIRED TO INCREASE SCHOOL BUS SAFETY?
HS-028 477

INCREASING

A CONCEPT OF INCREASING COMPATIBILITY OF PASSENGER CARS
HS-028 406

INDEPENDENT

DESIGN AND DEVELOPMENT OF AN INDEPENDENT REAR SUSPENSION FOR THE 1979 CADILLAC ELDORADO
HS-027 359

INDICATORS

INDICATORS OF DRIVER INATTENTION
HS-028 472

INDIRECT

INDIRECT VISIBILITY REQUIREMENTS FOR PASSENGER CARS
HS-028 460

INDUCED

THE IMPACT OF MOTOR VEHICLE INDUCED TRAUMA ON HOSPITAL USEAGE (SIC): AN EXPLORATORY STUDY
HS-028 488

INFANT

REARWARD-FACING INFANT RESTRAINTS: OPTIMUM RECLINING ANGLES FOR THE DESIGN OF SAFER, MORE PROTECTIVE AND COMFORTABLE RESTRAINTS
HS-028 500

INFLATABLE

THE INFLATABLE DIAGONAL BELT (IMPROVEMENT OF PROTECTION IN THE CASE OF FRONTAL IMPACT)
HS-028 408

INFLATOR

AIR BAG INFLATOR RELIABILITY
HS-805 257

INFORMATION

A PLAN FOR REGIONAL COOPERATION: PUBLIC INFORMATION AND EDUCATION FOR HIGHWAY SAFETY INCLUDING COMMUNICATIONS PLANS AND STRATEGIES. FINAL REPORT
HS-805 217

MOTOR VEHICLE BRAKING SYSTEMS AND COMPONENTS. STANDARDS, RECOMMENDED PRACTICES, INFORMATION REPORTS
HS-027 393

INJURIES

COLLISION CHARACTERISTICS AND INJURIES TO PEDESTRIANS IN REAL ACCIDENTS
HS-028 433

PREDICTION OF THORACIC INJURIES AS A FUNCTION OF OCCUPANT KINEMATICS
HS-028 413

INJURY

A PROTOTYPE LOAD-SENSING DUMMY FACEFORM TEST DEVICE FOR FACIAL INJURY HAZARD ASSESSMENT
HS-028 468

CAR DESIGN FOR PEDESTRIAN INJURY MINIMIZATION
HS-028 436

DEVELOPMENT OF A SIMPLIFIED VEHICLE PERFORMANCE REQUIREMENT FOR PEDESTRIAN INJURY MITIGATION
HS-028 444

PATTERNS OF INJURY IN PEDESTRIAN ACCIDENTS
HS-028 478

THE DEGREE OF BENEFIT OF BELTS IN REDUCING INJURY--AN ATTEMPT TO EXPLAIN STUDY DISCREPANCIES
HS-027 406

THE EFFECT ON INJURY AND FATALITY RATES DUE TO SEATBELT USAGE IN SASKATCHEWAN

THE V-SHAPED VEHICLE FRONT--ITS INFLUENCE ON INJURY SEVERITY IN PEDESTRIAN ACCIDENTS AND SIDE COLLISIONS
HS-028 427

INSPECTION
ULTRASONIC INSPECTION OF TEN RETREADED TIRES AND THIRTY-TWO CASINGS. FINAL REPORT
HS-805 019

INSTABILITY
ELIMINATING YAW INSTABILITY IN TRACTOR-SEMITRAILERS DURING CORNERING
HS-027 402

INSTRUCTION
HIGHWAY TRAFFIC SAFETY SELF-INSTRUCTION COURSE. MODULE 8 WORKBOOK. ADMINISTRATIVE EVALUATION. 1ST ED.
HS-900 038

INSTRUCTOR
COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. INSTRUCTOR'S GUIDE
HS-900 035

INSTRUMENTATION
EXPERIMENTAL APPLICATION OF ADVANCED THORACIC INSTRUMENTATION TECHNIQUES TO ANTHROPOMORPHIC TEST DEVICES
HS-028 418

INTEGRAL
INTEGRAL OR COMBINED BRAKING SYSTEM FOR MOTORCYCLES
HS-028 446

INTERIM
THE EFFECT OF AMBIENT TEMPERATURE VARIATION ON EMISSIONS AND FUEL ECONOMY--AN INTERIM REPORT
HS-027 401

INTERIOR
INTERIOR NOISE REDUCTION IN A RECREATIONAL VAN
HS-027 352

OCCUPANT PROTECTION IN INTERIOR IMPACTS. AN ANALYSIS OF FEDERAL MOTOR VEHICLE SAFETY STANDARD NO. 201
HS-028 493

INTERNAL
NUMERICAL PREDICTION OF AXISYMMETRIC LAMINAR AND TURBULENT FLOWS IN MOTORED, RECIPROCATING INTERNAL COMBUSTION ENGINES
HS-027 356

PREDICTION OF GAS EXCHANGE PROCESSES IN A SINGLE CYLINDER INTERNAL COMBUSTION ENGINE
HS-027 357

INTERNATIONAL
INTERNATIONAL TECHNICAL CONFERENCE (7TH) ON EXPERIMENTAL SAFETY VEHICLES, PARIS, JUNE 5-8, 1979
HS-805 199

INTERVENTION
COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. PARTICIPANT'S MANUAL
HS-900 034

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. INSTRUCTOR'S GUIDE
HS-900 035

INVESTIGATION
ACCIDENT INVESTIGATION TECHNIQUES FOR SECONDARY SAFETY
HS-028 430

ANALYSIS OF PEDESTRIAN ACCIDENTS TAKEN FROM A ROAD TRAFFIC ACCIDENT INVESTIGATION
HS-028 432

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. PARTICIPANT'S MANUAL
HS-900 034

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. INSTRUCTOR'S GUIDE
HS-900 035

INVESTIGATION OF OVERALL EFFICIENCY IN THE FIRST FEW HOURS OF A PUMP'S LIFE
HS-027 377

INVESTIGATIONS
A STUDY OF DRIVER CONTROL BEHAVIOR BASED ON ACCIDENT INVESTIGATIONS.
HS-028 434

INVOLVEMENT
A COMPARISON OF ALCOHOL INVOLVEMENT IN PEDESTRIANS AND PEDESTRIAN CASUALTIES
HS-028 463

KENTUCKY
AMERICAN ASSOCIATION FOR AUTOMOTIVE MEDICINE ANNUAL CONFERENCE (23RD) PROCEEDINGS, LOUISVILLE, KENTUCKY, OCT. 4-6, 1979
HS-028 462

KILLED
CHILDREN KILLED IN CRASHES
HS-028 491

KINEMATICS
PREDICTION OF THORACIC INJURIES AS A FUNCTION OF OCCUPANT KINEMATICS
HS-028 413

KNOWLEDGE
ALCOHOL AND HIGHWAY SAFETY 1978. A REVIEW OF THE STATE OF KNOWLEDGE. SUMMARY VOLUME
HS-805 172

LAMINAR
NUMERICAL PREDICTION OF AXISYMMETRIC LAMINAR AND TURBULENT FLOWS IN MOTORED, RECIPROCATING INTERNAL COMBUSTION ENGINES
HS-027 356

LAMP

AN OPTIMUM VISIBILITY DESIGN FOR THE STOP LAMP (BRAKE LIGHT)
HS-028 457

LATE

TRANSPORT FOR THE ELDERLY AND THE HANDICAPPED--AN OVERVIEW FROM THE LATE 70'S
HS-027 396

LATERAL

COMPATIBILITY OF MASSES AND STRUCTURES IN CAR-TO-CAR LATERAL COLLISIONS
HS-028 435

LATERAL COLLISION TESTS
HS-028 423

OCCUPANT PROTECTION IN LATERAL COLLISIONS: SPECIAL FEATURES OF RENAULT E.P.U.R.E. (ETUDE DE LA PROTÉCTION DES USAGERS DE LA ROUTE ET DE L'ENVIRONMENT) (EXPERIMENTAL SAFETY VEHICLE)
HS-028 425

SYNTHESIS OF HUMAN TOLERANCES OBTAINED FROM LATERAL IMPACT SIMULATIONS
HS-028 412

LEGISLATION

IS FURTHER LEGISLATION REQUIRED TO INCREASE SCHOOL BUS SAFETY?
HS-028 477

SAFETY BENEFITS OF THE SEAT BELT LEGISLATION AND SPEED LIMIT REDUCTION IN ONTARIO
HS-028 484

SEAT BELT LEGISLATION
HS-028 464

VEHICLE SAFETY CAR HANDLING AND BRAKING: LEGISLATION CAN NOT COVER EVERYTHING
HS-028 459

LEGISLATIVE

THE TENNESSEE CHILD PASSENGER PROTECTION ACT: ORIGIN, LEGISLATIVE SUCCESS, AND NATIONAL IMPACT
HS-028 467

LICENSING

THE EFFECT OF THE TEXAS MEDICAL ADVISORY BOARD FOR DRIVER LICENSING ON DRIVING PERFORMANCE
HS-028 479

LIFE

INVESTIGATION OF OVERALL EFFICIENCY IN THE FIRST FEW HOURS OF A PUMP'S LIFE
HS-027 377

LIGHT

AN OPTIMUM VISIBILITY DESIGN FOR THE STOP LAMP (BRAKE LIGHT)
HS-028 457

FINAL IMPACT ASSESSMENT OF THE LIGHT TRUCK AND VAN FUEL ECONOMY STANDARDS FOR MODEL YEARS 1980 AND 1981
HS-805 258

LIGHT TRUCK AND VAN FUEL ECONOMY STANDARDS FOR MODEL YEARS 1980 AND 1981. RULEMAKING SUPPORT PAPER SUPPLEMENT
HS-805 260

LIGHT TRUCK FUEL ECONOMY STANDARDS. MODEL YEAR 1981. RULEMAKING SUPPORT PAPER
HS-805 259

LIGHTING

IMPROVEMENT OF REAR AND FRONT LIGHTING SYSTEMS FOR MOTOR VEHICLES
HS-028 456

LIMIT

SAFETY BENEFITS OF THE SEAT BELT LEGISLATION AND SPEED LIMIT REDUCTION IN ONTARIO
HS-028 484

LIMITS

THE BIOMECHANICAL LIMITS OF SEAT BELT PROTECTION
HS-028 476

LITER

TURBOCHARGING FORD'S 2.3 LITER SPARK IGNITION ENGINE
HS-027 353

LOAD

A PROTOTYPE LOAD-SENSING DUMMY FACEFORM TEST DEVICE FOR FACIAL INJURY HAZARD ASSESSMENT
HS-028 468

LOCATION

MULTIPLE LOCATION RADIOACTIVE WEAR ANALYSIS TECHNIQUES
HS-027 383

LOOK

A FUNDAMENTAL LOOK AT SIDE IMPACT
HS-028 494

LOOP

POSSIBILITIES FOR IMPROVING SAFETY WITHIN THE DRIVER-VEHICLE-ENVIRONMENT CONTROL LOOP
HS-028 451

LOSS

RESULTS OF ENERGY-LOSS MEASUREMENTS ON PASSENGER CAR TIRES OPERATING IN THE FREE-ROLLING AND BRAKING/TRACTION MODES. FINAL REPORT
HS-805 224

LOUISVILLE

AMERICAN ASSOCIATION FOR AUTOMOTIVE MEDICINE ANNUAL CONFERENCE (23RD) PROCEEDINGS, LOUISVILLE, KENTUCKY, OCT. 4-6, 1979
HS-028 462

LOW

DISPERSION OF CARBON MONOXIDE FROM ROADWAYS AT LOW WIND SPEEDS
HS-027 338

LUBRICATION

A STUDY OF LUBRICATION CHARACTERISTICS ON VALVE STEM SEALS FOR AUTOMOBILE ENGINES
HS-027 345

MAJOR

WHO ARE USING CHILD RESTRAINT SYSTEMS AND WHY--DATA FROM FOUR MAJOR CANADIAN CITIES
HS-028 485

MANUAL

A MANUAL FOR DESIGN AND CONSTRUCTION OF BICYCLE PATH PAVEMENTS. FINAL REPORT
HS-027 409

A MANUAL OF ANTI-THEFT GUIDELINES FOR STATE MOTOR VEHICLE TITLING PROGRAMS
HS-805 198

COURT INTERVENTION: PRE-SENTENCE INVESTIGATION TECHNIQUES FOR DRINKING/DRIVING OFFENSES. PARTICIPANT'S MANUAL

Highway Safety Literature

U.S. Department of Transportation **National Highway Traffic Safety Administration**

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safe Administration (NHTSA). It is divided into the following sections: Abstract Citations, containi bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out- context (KWOC) list of words in the title, followed by the full title and HS number (our accessi number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Rep Number Index. In those months when information on contracts recently awarded is available, section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technic Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Edit at the address below for inclusion in the collection and abstracting in this publication. Plea indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for inf mation. Views expressed are those of the authors and not necessarily those of the Administ tion. Reference to brand names, equipment, models or companies does not imply endorsement NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Satety Literature** may be addressed to

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive gineers, Dept. HSL, 400 Co monwealth Drive, Warrenda Pa. 15096. Order by title and S report number.

TRB: Transportation Resea Board, National Academy Sciences, 2101 Constitution A N.W., Washington, D.C. 20418.

Corporate author: Inquiries sh be addressed to the organiza listed in the individual citation

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number ---- HS-013 124

Title of document ---- **MAXIMUM BRAKE PEDAL FORCES PRODUCED B**
MALE AND FEMALE DRIVERS

Abstract ---- The object of this research was to obtain data concerning t
maximum amount of brake pedal force that automobile driv
were able to sustain over a period of ten seconds. Subje
were told to apply the brakes in the test car as they would i
panic stop, and to exert as much force as possible on t
pedal over the entire ten second test period. A total of 84 s
jects were tested, including 42 males and 42 females. T
results indicated that there is a wide distribution of valu
which characterizes the pedal force that the subjects were a
to generate. Male subjects produced generally higher for
than did females. Over half the women tested were unable
exert more than 150 lbs. of force with either foot alone, b
when both feet were applied to the pedal, force levels rose s
nificantly.

NHTSA accession number ---- HS-018 924

Title of document ---- **NATURAL FREQUENCIES OF THE BIAS TIRE**

Abstract ---- The lowest natural frequencies of a bias tire under inflati
pressure are deduced by assuming the bias tire as a compos
structure of a bias-laminated, toroidal membrane shell a
rigorously taking three displacement components into co
sideration. The point collocation method is used to solve
derived system of differential equations with variable coe
cients. It is found that the lowest natural frequencies cal
lated for two kinds of bias tire agree well with the correspo
ing experimental results in a wide range of inflation pressu
Results of the approximate analysis show that the influen
of the in-plane inertia forces on natural frequency may be c
sidered small, but the influences of in-plane displacements
large, particularly on the natural frequency of the tire un
low inflation pressure.

MANUAL ON UNIFORM TRAFFIC CONTROL DEVICES FOR STREETS AND HIGHWAYS. 1978 ED.

The manual covers standards for all signs, signals, markings, and devices placed on, over, or adjacent to a street or highway by authority of a public body or official having jurisdiction to regulate, warn, or guide traffic. The material includes general provisions, signs (regulatory; warning; guide signs for conventional roads, expressways, and freeways; and signs for civil defense), markings (pavement and curb, object markers, delineation, colored pavements, and barricades and other channelizing devices), signals (traffic controls, warrants for installation, and pedestrian and other highway signals), and islands (design, approach end treatment, illumination, signs, and markings). Separate sections cover traffic controls for construction and maintenance operations, for school areas, for railroad-highway grade crossings, and for bicycle facilities. This edition of the manual incorporates all revisions which have been approved through official rulings, and continues a trend toward broader use of symbols rather than word messages.

TRAFFIC ACCIDENTS INVOLVING PSYCHIATRIC PATIENTS. CHARACTERISTICS OF ACCIDENTS INVOLVING DRIVERS WHO HAVE BEEN ADMITTED TO DANISH PSYCHIATRIC DEPARTMENTS

An analysis was made of injury-producing accidents involving psychiatric inpatients as drivers which occurred in Denmark during the Jul 1972-Jun 1974 period. Women were overrepresented among these drivers compared to the 1973 accident-involved (injury-producing) driver population in general. A great majority of the drivers in the psychiatric group were in the 25-54 age bracket. About 3% of the patients were involved in two or more accidents during the period studied. More of the patients drove stolen vehicles, did not have valid licenses, and did not use safety belts at the time of the accident than the other accident-involved drivers. Those in the psychiatric group were injured more frequently than the other group of drivers, and were more frequently intoxicated, with higher blood alcohol levels. They were most commonly diagnosed as having either personality disorders or transitory reactions.

EVALUATION OF SAFETY SYMBOLS

The increasing use of symbols to convey fire safety information, and the trend toward international standardization of symbols for transportation and other systems are described. The need for further research on symbols is discussed in terms of their advantages (rapid and accurate communication without the barriers of verbal language) and disadvantages (too rapid proliferation of different symbols and inappropriate or misleading application). The failure to evaluate the comprehensibility of each symbol is cited as a major problem. A case study which illustrates the issues surrounding a proposed set of fire safety symbols is presented. The symbols studied were drawn from the draft standard proposed by the International Standards Organization Technical Com. 21 subcommittee on Fire Safety Symbols. This study, sponsored by the National Fire Prevention Assoc., evaluated 22 fire safety symbols for their accuracy and ability to convey information. Preliminary results show that several of the symbols were accurately understood by the majority of subjects, but others were either not known or were identified with a meaning opposite to that intended. The 22 symbols are illustrated, with notation of the percentage of subjects who responded correctly. A current National Bureau of Standards safety symbol evaluation program is described.

AIR QUALITY IMPACTS OF TRANSIT IMPROVEMENT, PREFERENTIAL LANE, AND CARPOOL/VANPOOL PROGRAMS. FINAL REPORT

A literature review (bibliography not included) was conducted of relevant demonstration and operational projects and analytical/model-based evaluations of three types of short-range transportation programs: priority treatment for high-occupancy vehicles on freeways and arterials; areawide carpool and van pool programs; and transit fare reductions and service improvements. Transportation programs which demonstrated potential for cost-effectively improving either localized or regional air quality were selected for detailed analysis. Twenty scenarios (ten local, ten regional) were defined to represent real-world circumstances. The travel, emissions, air quality, energy consumption, economic, and cost impacts for the programs and scenarios were analyzed. The cost-effectiveness of the alternative programs in promoting air quality and reducing vehicular emissions was examined. Important factors (e.g. meterological conditions, traffic volumes and speeds, and changes in modal choice) likely to influence air quality and emissions were considered. The information developed is intended to assist urban areas in developing transportation measures for the State Implementation Plan and integrating their transportation system management and air quality planning programs as required by the Federal Hwy. Administration, Urban Mass Transportation Administration, and Environmental Protection Agency. Appended are analytical assumptions and methodology for non-cost impact estimates and a set of unit cost assumptions.

TREATMENT IN AN ALCOHOLISM AND DRUG ADDICTION UNIT

The admission status, social and demographic characteristics, and treatment course are described for 359 patients treated in the alcoholism and drug addiction unit at Cherry Farm Hospital, Dunedin, New Zealand, from Mar 1974 to Feb 1977. Persons dependent on alcohol alone, those dependent on drugs other than or in addition to alcohol, and those with mental or physical conditions where drug dependence was a prominent feature were admitted to this unit on an informal or on a compulsory basis. The treatment goal for all patients was abstinence. A sample of 156 of these patients leaving the unit was followed for 12 months to assess treatment outcome. It was found that one year after discharge, 11% of the patients had adopted an abstinent lifestyle while 42% had been rehospitalized. It was found that compulsory enrollment status was not related to outcome status, nor was it related to employment, domicile, marital status, or cultural background. Discharged women were significantly more likely to achieve abstinence than men and less likely to be rehospitalized. No relationship was found between previous treatment and outcome. Some relationship was found between marital status and outcome status for women, but not for men. Strong relationships were determined between both occupational status and insight and the status of outcome. Recommendations from this study include: consideration of a variety of outpatient services which would reduce the need for hospital admissions and re-admission for both compulsory and informal patients; use of a number of individually formulated goals vs. use of abstinence as the only specified goal, and incorporation of an evaluation process as an integral part of any treatment program.

EXPLOSION OF AUTOMOBILE BATTERIES AS A CAUSE OF OCULAR TRAUMA

A 33-year-old man suffered ocular trauma as the result of an automobile battery explosion. The subject was checking the level of the battery acid using a lighted match as a source of illumination when the battery exploded. The central corneal epithelium was peeled back to the limbus in both of the patient's eyes. There was a 3 mm laceration of the nasal bulbar conjunctiva of the right eye. On ophthalmoscopy, macular edema; subretinal, preretinal, and vitreous hemorrhages; and a choroidal rupture were seen in the right eye. During hospitalization, an area of stromal edema developed in the right cornea. Both corneas subsequently re-epithelialized. Six weeks after the accident the hemorrhages were slowly resorbing. A hole had developed in the macular area of the eye over an area of subretinal hemorrhage. Conjunctival laceration and choroidal rupture seen in another case resulted in the rupture of the globe and subsequent loss of the eye. According to evidence, most ocular injuries caused by battery explosions occur when a person uses an open flame to check the battery acid level. Theoretically, such explosions can occur only if a recent discharge of the battery (as occurs when starting a car) has initiated release of hydrogen gas. Internal sparking and improper use of jumper cables can also ignite hydrogen gas, causing battery explosions.

THE $200 MILLION CAR

John Z. DeLorean, a former executive with General Moto
has established his own company to produce a two-seat spo
car tentatively named the DMC-12. By the beginning of 198
the DMC-12 is scheduled to roll off a Northern Ireland asse
bly line. The car will be in the Corvette-Porsche 924 pri
range of $14,000, and features a stainless steel skin which
expected to last at least 25 years without rust. The body chas
is made of a new molding process with glass fiber and ureth
foam saturated with resin. The chassis is light but strong, with
front design aimed at providing occupant protection in 80 m
crashes. The DMC-12's gull-wing doors are regarded as saf
than conventional ones because they are not jarred open
easily. Mileage is expected to be 32 mpg highway and 28 m
city; acceleration is projected to be 0 to 60 mph in less th
eight sec. Except for the chassis, DeLorean's company will
little manufacturing. The V-6 engines are being obtained fro
Renault, air conditioning from General Motors, and tires fro
either Pirelli or Goodyear. The limited options include automa
ic or five-speed transmission and choice of interior color. Th
greatest obstacle in producing the car proved to be financin
but DeLorean was able to obtain $200 million from vario
investors and $120 million in development grants from the go
ernment of Northern Ireland. By the end of 1979, a network
400 dealerships for the DMC-12 is expected (located mostly
California and Texas, and involving General Motors dealers
By 1982, the company expects to produce 30,000 cars per ye
and to employ 2000 workers.

A STRUCTURAL SURVEY OF CLASSES OF VEHICLES (RAIL EQUIPMENT) FOR CRASHWORTHINESS. FINAL REPORT

A three-phase study was conducted to evaluate and improve t
crashworthiness of several classes of passenger-carrying rail v
hicles. Phase 1 surveyed the train-to-train accident data fro
1966 through 1973, identified the principal factors in cras
worthiness and personal injury, prioritized the vehicles f
study, and defined candidate improvements in terms of co
benefit. A detailed analysis of the structural integrity of a co
muter car (the St. Louis Car Co., ICG Highliner) was p
formed. Phase 2 extended the structural analysis to the caboo
(International Car Co., Bay Window Caboose) and the locom
tive (Electromotive Div. of General Motors, GP-40 mode
Phase 3 developed a potential design for a structurally cras
worthy locomotive cab (the locomotive having been found
be the most lethal vehicle). This design treats a deflection shie
system suitable for concept validation testing, and throu
mathematical modeling it provides both static and dynamic an
yses to assist in the detail specifications of the required str
tures. Recommendations from this study include: further dev

opment of analytical tools for collision dynamics and structure behavior in crashes and application to design evaluation; development of crashworthy components (e.g. couplers, anticlimbers, collision posts, and truck retention devices); static and dynamic testing of vehicle classes to determine failure modes; establishment of specifications and standards for crash-resistant welds for structural elements; development of procedures for obtaining impact-resistant steel structural shapes; and installation and validation testing of the deflection shield system on a locomotive.

LEGAL BUT LETHAL (BRITISH TIRE LAWS)

The Firestone Tyre and Rubber Co. (U.K.) advocates a change in the Motor Vehicles (Construction and Use) Regulation regarding tire tread depth. According to the law, a tire can be considered illegal if it does not have a tread depth of at least 1 mm throughout at least three-quarters of the breadth of the tread and around the entire outer circumference. Firestone considers this requirement not only inadequate but difficult to interpret. There remain the questions of where tread begins and ends on a radial tire, and whether the three-quarters breadth measurement needs to be uninterrupted across the arc of the tread. A modification of the regulation is recommended to require a minimum 1.59 mm of pattern depth across 100% of the tread. Firestone also acknowledges the need for an increased effort by the tire industry to convince motorists that worn tires are very dangerous.

CARS AND ROADS: UP-TO-DATE OR OBSOLETE?

The opinion is advanced that the car and the roadway of today are obsolete and need rethinking and redesigning. The automobile was developed by Henry Ford as a means for farmers to travel to market and to escape the isolation of the country and was never intended for city streets. Cars today are used mainly on 30 mph urban streets, where pedestrians abound. Just as cars are not designed for in-town travel, city streets are not designed to be shared by people and vehicles. Walking is an overwhelmingly important form of transport and a key element in the economy of the cities. About two out of five trips in Britain are made on foot. Two out of three children walk to school and one out of five adults walks to work. Yet the pedestrian has been neglected by policy makers; the failure to create safe and convenient conditions for pedestrians is expressed in road casualty figures. In Britain in 1977, 35% of the road fatalities involved pedestrians. The aim of the Pedestrians Assoc. (Great Britain) is to reshape the car and the roadway to make them compatible with pedestrian safety and comfort.

THE DIFFICULT AGE (SAFETY RESTRAINTS FOR CHILDREN)

Research was carried out by Dr. Bertil Aldman, Professor of Traffic Safety at Chalmers Univ., Goteborg, Sweden, on child injuries and the use of safety belts. Dr. Aldman considered how physical growth influences the behavior of the child's body during a car accident. His studies, conducted on behalf of Volvo, concluded that one type of protective system for all children is not possible. Any system should prevent the child from being flung about in the car, and preferably should make use of the energy-absorbing properties of the car structure. Volvo's recommendations for child occupant protection are presented. For children up to the age of nine months, the carry cot and safety bench are suggested. For ages ten months through six years of age, a rearward-facing child restraint seat is recommended, and for ages seven through ten years, a seat belt cushion anchored to the back seat by available seat belts.

DIESEL ENGINE THERMAL LOADING

Twelve papers are compiled from the SAE off-highway vehicle meeting in Milwaukee, 10-13 Sep 1979. The papers cover a wide range of subjects in the general area of diesel engine heat transfer and thermal loading. Topics are as follows: Norwegian research on thermal loading of diesel engines; strength analysis of thermally loaded engine components by two- and three-dimensional finite element models; prediction of thermal loading of supercharged diesel engines; effect of partial suppression of heat loss to coolant on the high-output diesel engine cycle; matching calculations for turbocharged and compound engines with reduced heat loss; advanced approaches for heat transfer calculations; heat transfer in the indirect injection diesel engine; instantaneous heat transfer in the cylinder of a high-speed diesel engine; determination of local heat transfer coefficients at the piston of a high-speed diesel engine by evaluation of measured temperature distribution; design and fatigue life of pistons for high brake mean effective pressure diesel engines; new design features, analytical methods, and research and development programs for diesel pistons; and use of photoelasticity in the analysis of engine components.

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY

Background is provided on Norwegian research in the field of thermal loading of large and medium speed diesel engines. Current research activities and typical results are discussed. Instrumentation employed in this research is described, with emphasis on sensors used in combustion chamber heat transfer studies. The use of minicomputers for data acquisition, processing, and presentation is discussed, as well as finite element analysis of temperature fields and heat transfer. Current research projects involve process modeling, electronic fuel injection, thermal-insulating coatings on engine components, combustion characteristics of heavy fuels, and thermal loading of medium-speed diesel engines. Supporting illustrations, graphs, and references are included.

STRENGTH ANALYSIS OF THERMALLY LOADED ENGINE COMPONENTS BY TWO-DIMENSIONAL AND THREE-DIMENSIONAL FINITE ELEMENT MODELS

Design analyses of thermally loaded engine components by two- rather than three-dimensional finite element models can reduce costs by at least an order of magnitude, although in some cases the significance of the results is also diminished or even lost. The effects of such simplifications are discussed using a diesel engine piston and a radial turbine wheel as examples. Temperature distributions can be computed with good accuracy using simplified models and engineering judgment. The results of stress analyses are much more uncertain. Even widely accepted idealizations can produce results which are directly misleading. Appended are descriptions of the fundamental considerations underlying the finite element programs as well as supporting illustrations.

PREDICTION OF THERMAL LOADING OF SUPERCHARGED DIESEL ENGINES

Experimental investigations were carried out on a high-speed diesel engine. Heat fluxes to the piston, cylinder head, and liner were separately determined by evaluating heat balances and measured steady-state temperature fields. The experimental results were compared with those of the following cycle simulations using an equation for the local mean heat transfer coefficient (Woschni (1967), SAE-670931): flux from the working fluid to the component, heat from the working fluid to the component, and heat transfer at the cooled side of the component. It was found that this equation can be used for predicting the heat losses to the cylinder walls as well as the steady-state temperature fields of the components.

HS-027 427

EFFECT OF PARTIAL SUPPRESSION OF HEAT LOSS TO COOLANT ON THE HIGH OUTPUT DIESEL ENGINE CYCLE

The effect of partial cylinder insulation was analyzed for a high-output diesel engine (Perkins 6.354 six-cylinder four-cycle) using the diesel cycle simulation program for three conditions: "normal" cylinder walls; walls with a uniformly distributed layer of silicon nitride, giving approximately isothermal conditions; and adiabatic wall conditions. For the case of the silicon nitride coatings, it was found that heat loss to the coolant can be reduced by approximately 50%. Isothermal operation of the engine brings about little improvement in indicated thermal efficiency, the reduced heat loss to coolant being largely transferred to increased exhaust enthalpy. The benefit of increased exhaust enthalpy can be fully realized only by turbocompounding. Adiabatic operation provides marked improvement in cycle efficiency as well as raised exhaust enthalpy. The requirement for fully adiabatic operation presents great practical difficulties in terms of materials and methods of construction.

HS-027 428

RESULTS OF MATCHING CALCULATIONS FOR TURBOCHARGED AND COMPOUND ENGINES WITH REDUCED HEAT LOSS

Matching analysis results are presented showing the effect of reduced heat loss on the interaction between a diesel engine and turbomachinery components. The engine used is the Perkins 6.354 six-cylinder with low compression ratio pistons. Results are given for a speed range between 1000 and 2500 rpm for both simple turbocharged and turbocharged compound engines with normal heat loss and with 50% heat suppression. The use of turbocompounding increases thermal efficiency by 2% to 3%. Compounding significantly improves the matching of the turbocharger by enabling a smaller turbine to be fitted, with improved air-fuel ratio, higher efficiency and less smoke at low engine speeds. Suppression of heat loss alone (realistic case) yields a 1% improvement in efficiency. On the other hand, true adiabatic operation would result in much larger gains (8% to 10%), particularly at low speeds. Alternative forms of compounding, such as the use of variable geometry turbines and split power arrangements, merit serious consideration.

ADVANCED APPROACHES FOR HEAT TRANSFER CALCULATIONS

Three advanced measuring techniques (and results of their application) for heat transfer in diesel engines are described: the surface temperature method, the heat flux probe application, and the combustion chamber pressure measurement method. Using results of experiments which applied these procedures, an improved heat transfer calculation method was developed. A comparison between measured and computed results showed that the equation defines heat transfer with sufficient accuracy for all engine operating conditions. The heat transfer equation is relatively simple and applies to high-pressure and charge cycle conditions. Information is supplied on the local mean heat transfer; further studies are necessary to determine the reasons for local differences (induced air motion or combustion), so that analogous computations can be made.

HEAT TRANSFER IN THE INDIRECT DIESEL ENGINE

A method is presented for predicting instantaneous heat transfer between the working fluid of an indirect injection diesel engine and pre- and main-chamber surfaces. The correlation is proposed for both motored and fired engine operation and is supported by experimental data. The model is based on the conventional Nusselt-Reynolds number relationship for the convective component, but uses a novel approach for the local characteristic velocity component. Under fired conditions, velocity enhancement is included, together with a radiation model. An experimental program of instantaneous heat flux measurement in the pre- and main-chamber is described which covers a wide range of operating conditions, both motored and fired. Comparisons of measured and predicted heat fluxes in both chambers are provided. Mean values of pre- and main-chamber surface temperature, and connecting passage wall temperatures are included.

HS-027 431

EXPERIMENTAL INVESTIGATION OF THE INSTANTANEOUS HEAT TRANSFER IN THE CYLINDER OF A HIGH SPEED DIESEL ENGINE

Measurements of instantaneous surface temperature variations were made at five positions on the combustion chamber side of the cylinder head in an externally supercharged, single-cylinder, four-stroke, high-speed diesel engine. Local instantaneous heat flux into the combustion chamber wall was calculated from the measured time curves of the local surface temperatures. It is assumed that the thermal conductivity of the material and a second temperature are known, and that the temperature field in the wall is one-dimensional. The total heat flux consists of a steady-state and a fluctuating component. The steady-state component requires the assumption of one dimensionality, whereas the fluctuating component does not. Since a one-dimensional temperature field in the wall cannot be realized, the measured steady-state component has to be corrected. A convenient correction method is described, and measured local and local mean heat transfer coefficient variations are presented, as well as variations calculated using Woschni's equation (1967, SAE-670931). Agreement is good between measured and calculated results for the high-pressure phase of the cycle.

DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION

More than 60 temperature distributions in a piston of a high-speed diesel engine were determined from measured temperatures at 20 discrete points of the piston for varied engine operating conditions and different cooling conditions. They were evaluated to determine the heat flux through the piston and the heat transfer coefficients at the boundaries. The results obtained are mutually conclusive and show that the heat flow from the working fluid to the piston for different engine operating conditions can be determined by a combined application of the cycle simulation and the electrolytic tank analog. The heat transfer coefficients at the cooled side of the piston are important for predicting the thermal loading of engine components.

DESIGN AND FATIGUE LIFE EVALUATION OF PISTONS FOR HIGH BMEP (BRAKE MEAN EFFECTIVE PRESSURE) DIESEL ENGINES

Anticipating an increase in the mean effective pressures (mep) of turbocharged diesel engines, designers expect that the standard cast aluminum piston with ring carrier, uncooled or splash-cooled, may become subjected to critical stress levels. The piston loading limit varies from 10 to a maximum of 14 bar mep. Before changing to alternative design principles, the load-bearing capacity of the aluminum piston could be improved by hard anodizing the crown, employing an internal cooling system, and also by roller burnishing the pin bore, using an inclined boss design or profile ground piston pin. The load limit could thus be extended to a range of 12 to 17 bar mep. Currently, nodular cast iron pistons in "monobloc" design have successfully been introduced at ratings of 16 to 22 bar mep. An upper limit of this piston design has not been defined. Results are presented of three-dimensional finite element analyses of the aluminum and cast iron piston structures.

SOME DIESEL PISTON FEATURES IN DESIGN ANALYSIS AND EXPERIMENT

A general view is presented of the state of the art of high-speed diesel engine piston design practice. Selective consideration is given to new features, analytical techniques, and research programs. Four computer-assisted predictive practices which are currently being successfully applied to piston development are described: cycle simulation, finite element analysis, transverse piston movement analysis, and cooling oil flow prediction. The application of these predictive methods has proved effective in solving problems, reducing development time and cost, and generally supporting cost-effective design. A better understanding of the ring pack sealing process is needed for the optimization of such factors as oil control, blowby, emissions, fuel consumption, and carbon deposit formation. Subjects important in current piston development activities are examined in some detail, with reference made to predictive methods and experimental programs. These areas include: oil cooling, crown cracking, close clearance designs, and land/groove features.

INVESTIGATIONS OF ENGINE COMPONENTS BY MEANS OF PHOTOELASTICITY

The application of photoelasticity to stress and deformation analysis of engine components is discussed, including four examples of the application of the two-dimensional photoel method: composite pistons, cooling-channel pistons, piston circlips, and crankshaft. Application of the three-dimensi photoelastic method includes diesel pistons for commercial v cles, composite pistons, nodular cast iron pistons, connec rods, shrinkage stresses in piston material due to cast iron st and piston pins with transverse bores. The two photoel methods are compared and they, in turn, are compared with finite element analysis method. The photoelastic surface l method, which can be applied in both static and dynamic in tigations of component stress, is described and two exan applications outlined (filter housing, engine block).

GASOHOL CONSUMPTION SKYROCKETS. TRY LITTLE "WHITE LIGHTNING" IN YOUR TANK

The current increase in gasohol use is primarily the result two factors, the skyrocketing cost of petroleum and recent g surpluses, particularly in corn-producing states. Factors rela to gasohol's popularity include driver-perceived improvemen automobile performance. Gasohol has a higher octane than leaded regular gasoline, resulting in reduced engine knock; cheaper than premium unleaded gasoline; and is a vehicle derived from renewable agricultural products. Extensive on the performance of a wide range of vehicles have indica no major problems with gasohol use. Three alcohol produ plan to expand or are expanding their facilities for eth production to accommodate the demand for gasohol. There been controversy over using 190- and 193-proof ethanol (w contains 5% water by volume) for gasoline blends becaus possible phase separation problems. This issue will become n when a new technology is used which can produce anhyd ethanol at relatively low cost from both 190- and 193-p ethanol. No food/fuel conflict is expected; in most instan alcohol is and will continue to be a co-product of food-pro tion processes. The use of methanol in blending gasohol is seen as economically feasible. A General Motors (GM) Labs. fuels expert says that gasohol has about 3% less en than gasoline, but if an engine were designed to run on alcohol, increased mpg could be achieved. According to the production of ethanol consumes more energy than is av ble in the alcohol it produces. The Dept. of Energy rema strong proponent of gasohol, while the auto industry sup coal and oil shale exploitation to meet fuel needs.

THE 80S. STANDARDS FORCE MOVE TO ELECTRONIC ENGINE CONTROLS

Electronic engine controls (EEC) are becoming more sop cated in an effort to maintain a stoichiometric balance be stricter fuel economy and emission standards for optimun ciency. An emerging EEC trend is the switch from analog to digital microprocessors. With an electronic control unit on board, electronic fuel injection (EFI) is a natural addition. Ford's EFI system replaces the carburetor on the 5.0 L engine in certain applications. This system is controlled by the EEC III (digital) which controls fuel discharge very precisely; combined with high fuel pressure, the fuel distribution to each cylinder is better than that achieved by a carburetor. This enables the engine to meet the stricter emission standards while retaining good driveability. Cadillac's EFI, also a throttle body system, uses a digital microprocessor which monitors fuel flow, spark advance, and manifold absolute pressure. The microprocessor limits idle speed to 500 rpm at all loads, and performs various diagnostic functions. With Chrysler's electronic feedback carburetor system, sensors in the exhaust manifold monitor oxygen content in the exhaust and relay that information to the computer. The computer adjusts the air-fuel mixture to maintain stoichiometry. The feedback carburetor is also used with an air pump and three-way catalyst to control emissions. For meeting California emission standards and for high altitude use, Chrysler has added a detonation suppressor system, in which sensors on the intake manifold monitor engine vibration levels and adjust the spark timing in response.

CONSUMERS' RESPONSES TO FUEL-EFFICIENT VEHICLES: A CRITICAL REVIEW OF ECONOMETRIC STUDIES

Previous economic research on automobile demand is reviewed and examined in terms of the response of consumers to fuel-efficient vehicles. Three categories of research are reviewed: aggregate and disaggregate econometric studies, and hedonic price analyses. It is shown that the fundamental problems encountered in all of the previous research were insufficient variation and too large covariation among automobile characteristics (e.g. price, weight, and length). Two methods to alleviate these problems are proposed for future research: a disaggregate model estimated with a large number of automobile alternatives (each make, model, and year) and no (or few) alternative-specific constants; and various experimental methods, such as conjoint analysis, to elicit consumers' values of various automobile characteristics.

A RAPID, SYSTEMATIC, AND COMPREHENSIVE CLASSIFICATION SYSTEM FOR THE IDENTIFICATION AND COMPARISON OF MOTOR VEHICLE PAINT SAMPLES. 1: THE NATURE AND SCOPE OF THE CLASSIFICATION SYSTEM

A computerizable classification for identifying car and truck paint was developed from data on 10,000 paint samples as well as information from manufacturers and paint vendors. Data were obtained from police traffic divisions in Alberta, Canada, for 1960-1977 North American and imported cars and trucks involved in accidents in Alberta over a 7-month period. A manual data retrieval system was designed to correlate microscopic and chemical information obtained from paint chip examinations and manufacturer information. Extensive codes and abbreviations were devised to collect, file, and correlate data from the 10,000 samples so that each information item could be independently and rapidly retrieved. Information items included vehicle line/series, years, assembly plants, and partial vehicle identification numbers for identifying hit-and-run vehicles. Industrial standardized conditions were used for microscopic comparisons of chromatic and geometric appearances. Infrared analysis was employed to investigate original topcoat and undercoat layers from secondary undercoat standards. After chemical analysis was complete, secondary undercoat standards were microscopically compared to correlate data from all assembly plants and model years. Each undercoat layer was color-coded and recorded in master files to facilitate access to data banks via computer. While paint samples were sorted into a set of working standards, it became obvious that surface geometric attributes played a major role in identifying and comparing samples (paint samples from the same model year and assembly plant exhibited wide variations in gloss and texture).

AN INVESTIGATION OF THE VARIABILITY OF GASOLINE CONSUMPTION AMONG STATES

Variations in state gasoline consumption rates per household and per vehicle are explained. The analysis assumes that the gasoline demand equation is the same for all states, and the Least Squares Dummy Variable (LSDV) approach is used to deal with time series (1966-1975) cross-sectional state data. The LSDV technique introduces a dummy variable for each cross-sectional unit except one which serves as a reference state. Regression analysis findings concern vehicle miles of travel, fuel intensity, gasoline exports, and agricultural gasoline use. A series of gasoline consumption rates is documented, ranging from a low of 588.7 gallons per vehicle (Pennsylvania) and 864.5 gallons per household (New York) to 900 gallons per vehicle (Arkansas) and 2,222 gallons per household (Wyoming). State household gasoline consumption rates are negatively related to population density, urbanization, agricultural employment, severe winter weather, and small car share of the vehicle fleet. Rates are positively related to the working age population and tourist activity level. Important differences in state gasoline use are not attributable to vehicle ownership, rate of licensed drivers, household size, differences in fuel price or income, and the truck-auto fleet mix. It appears that state consumption rates are caused by complex interactions among environmental, demographic, and economic factors.

ENERGY INTENSITY AND RELATED PARAMETERS OF SELECTED TRANSPORTATION MODES: PASSENGER MOVEMENTS

A study was undertaken to determine causes of divergences among published energy intensity values of selected transportation modes and to prepare a set of consistent values. The focus is on passenger movement by air, automobile, bus, and rail. Federal Hwy. Administration estimates of automobile energy intensity are based on state estimates of vehicle miles traveled, which may contain substatial errors. Environmental Protection Agency (EPA) certification tests have been diverging more each year from actual on-road fuel economy. In studies undertaken to quantify divergences and to determine their causes, a series of regression equations was developed that may be used to correct EPA values in relation to on-road performance. These equations yield correction factors of 0.5, 1.3, 2.3, and 3.5 mpg for model year 1974-1977 cars, respectively, for the EPA sales-weighted fuel economy. With this information and other related data, one can estimate automobile energy intensities for both urban and intercity driving environments. Much information is available about the disaggregate influence of operational and engineering parameters on automotive fuel economy: a 10% change in gross vehicle weight results in a 4% change in fuel economy with all other factors unchanged; a 10% reduction in aerodynamic drag yields a 2-3% improvement in fuel economy; necessary engine maintenance yields close to a 5% improvement in fuel economy; and short trip lengths are associated with severe fuel economy penalities due to insufficiet engine warm-up. Buses combine the auto's flexibility with inherent efficiencies of operating larger capacity vehicles, with intercity buses being the most energy-efficient transportation mode available. The effect of speed on energy consumption varies with terrain (flat, rolling, hilly). A consistent time series of operational data and energy intensity values is presented for each transportation mode.

COLOUR VISION DEFICIENCIES IN ROAD TRAFFIC

Various references are cited to illustrate the diversity in opinion regarding the extent to which drivers with color vision defects, especially protanopia, are a traffic safety hazard. Some proposals which have been made are considered inadequate to make the traffic color code system safer for these drivers. These proposals include use of a red-green-blue color code, doubling the green signal, use of flashing red lights, use of triangular and square diaphragms in traffic lights, and use of green or blue brake lights. Possibly more effective solutions include all visibility and conspicuity improvements of road safety targets (e.g. bigger and more intense traffic lights), greater diameter of the red traffic light, and green lights close to the blue boundary. It is mentioned that visual perception of color-defective drivers can be further impaired by absorbent glasses (sunglasses, tinted contact lenses, and tinted windshields). It is stated that acquired color vision defects not detected by usual color vision tests, and the influence of noise, hypoxemia, and fatigue on normal and defective color vision are only of secondary importance in road traffic safety. A research project sponsored by the Austrian government is described which will test 100 normal and 100 color-defective subjects by a detailed ophthalmological exa
tion, and by a psychological test to determine to what e
color vision defects affect traffic safety. Police records of
dents caused by drivers with color vision defects will be
lyzed, and a field study will compare the driving behavi
drivers with color vision defects (protanomals, protanopes,
teranomals, and deuteranopes) to that of drivers with no
vision.

SAFETY RESTRAINTS FOR CHILDREN IN AUTOMOBILES: WHO USES THEM?

From a sub-sample of 318 Monroe County, N.Y. househ
interviewed by telephone in 1969 (basic sample 514 fami
information on about 150 families was examined to investi
the relationship between child restraint use and demogra
characteristics and exposure to stress. It is believed that i
mation of this type would delimit a target population at risk
would indicate the type of public education most likely t
effective. Mother's age was found to be related to restraint
only by children under age ten; the absence of any relation
for mothers of children age 11 and older suggests a decli
influence of the parent on this aspect of child behavior.
children under the age of six, the older the mother was, the
likely she was to use a child restraint. Reported non-use
restraints were also found most often to be less educated
have a lower income, and to be Catholic. Use was also fou
be less among those subjected to a high degree of stress (
term, such as chronic illness or unemployment, and short-
such as "upsetting events").

ROAD ACCIDENTS: ARE DRUGS OTHER THAN ALCOHOL A HAZARD?

It is pointed out that the effects of drugs other than alcoh
driving behavior are more difficult to determine because
metabolism is more complex, the blood concentration ten
be less directly related to their effects, and responses m
more idiosyncratic. Various survey studies in the U.S., Ca
and U.K. are reported which investigated the relationshi
tween the use of various prescribed drugs (taken with or
out alcohol) and traffic accidents, and the extent of drug (
cation) use among the driver population. Although many p
will be safer driving with than without medication, even a
drug effect may be hazardous in a tricky situation. B
having doctors inform their patients of regular and a
effects and interactions of the drugs they prescribe, it is r
mended that posters on drug effects should be used in ho
and health centers, that the media educate the public on
risks, and that drug containers be labeled accordingly

accident risk of marijuana use, and the increasing problem of multiple drug abuse are noted.

A SURVEY OF RHODE ISLAND MOTORCYCLE FATALITIES DURING 1975-1976

Epidemiological factors and injury patterns with respect to helmet use are reported for the 30 motorcycle fatalities which occurred during 1975-1976 in Rhode Island. The state repealed its mandatory helmet use law in Jun 1976. It appears that the annual number of motorcycle fatalities in the state is rising, but further studies are needed to determine the fatality rate increase. The vast majority of victims were white males in their mid-twenties. More than half of the victims were not licensed to operate a motorcycle. Although statistics for these two years indicate that reduced helmet usage was accompanied by a reduced incidence of head/neck trauma among fatalities, a cause-and-effect relationship does not necessarily exist. It is emphasized that data derived from survivors of motorcycle accidents may yield more specific information concerning the safety effects of helmet use, and would supply useful data regarding the "helmet debate". An addendum notes that during 1977 compared to the previous two years, there was an increase in total fatalities, a decrease in operators wearing helmets, but a similar number dying from head trauma. There was a decrease in alcohol use, but no change in other drug use.

SPINAL CORD INJURIES AS A RESULT OF MOTORCYCLE ACCIDENTS

Twenty-one clinical cases are reported of spinal cord injuries (orthopedic and neurological) sustained in motorcycle accidents. The cases were admitted to the Spinal Cord Injury Centre at the Conradie Hosp., Pinelands, South Africa, between 1963 and 1977. These cases represented 3% of such injury cases resulting from motor vehicle accidents which were admitted to the hospital during that period. This type of injury has increased in the area since 1973; it is most common among 15- to 20-year-olds, and is sustained mostly during the summer months. The upper thoracic spine is the most common injury site, maximally involving the sixth thoracic vertebra. The motorcyclist usually sustained this type of injury when he was thrown from his bike, landing on his head or the upper part of his back. The thoracic vertebral injuries were equally distributed between compression fractures and fracture-dislocations. Seventy-five percent involved more than one thoracic vertebral level. The majority (81%) of the neurological injuries of the thoracic spinal cord and 61% of the cervical spinal cord injuries were complete. Wearing of standardized crash helmets became compulsory in 1973, resulting in a decreased mortality due to associated head injuries, and in an increasing percentage of spinal injuries.

CAUSES AND PREVENTION OF ROAD ACCIDENTS

From the perspective of the British experience, especially in the Gwent area of England, the causes, characteristics, and prevention of traffic accidents are outlined. The influence of driver age, sex, and driving experience on accident susceptibility is considered, as well as the effect of the physical and mental condition of the driver. The reduced impact of the breathalyzer test introduced in Britain in 1967 (the legal blood alcohol level limit being 80 mg/100 ml) is noted, as well as the effect of many drugs besides powerful narcotics on driving ability (e.g. cough syrups or insulin). Accident cases are cited which were caused by momentary distractions of drivers or pedestrians. The characteristics of pedestrian accidents involving adults are compared with those involving children; particular mention is made of child pedestrian accidents involving ice cream trucks, and accidents at pedestrian crosswalks. Other accident factors are outlined, such as vehicle ownership, road unfamiliarity, journey type, seat belt use, and lighting. The traffic safety activities of the Royal Society for the Prevention of Accidents, the police (Gwent Constabulary), and the Dept. of the Environment are described. The effects of a traffic jam on a driver's blood pressure and pulse rate are shown. It is concluded that accident prevention requires a reduction in problems presented by the environment and an improvement of the road user's ability to cope (reduction in human error).

A GUIDE TO REPORTING HIGHWAY STATISTICS

Procedures are outlined for use by the states in the compilation, analysis, and reporting (to the Federal Hwy. Administration (FHWA)) of two categories of data: state motor fuel, motor vehicle, and driver license data; and highway finance data of state and local governments. Detailed instructions are provided for the preparation and submission of annual reporting forms to account for fuel consumption, vehicle registrations, driver licensing, and motor carrier taxation; and the source, distribution, and expenditures of highway funds. The major reporting forms are cross-referenced to the chapters that discuss them. This guide, together with its companion volume, is intended to explain the rationale and procedures involved in the national reporting system for highway statistics.

EFFECTS OF SEATBELT LEGISLATION AND REDUCTION OF HIGHWAY SPEED LIMITS IN ONTARIO

The background of the mandatory seat belt use law and the highway speed limit reduction in Ontario, Canada is reviewed, and some statistics are presented to demonstrate the positive effect of this legislation on highway safety. On 1 Jan 1976, Ontario enacted a law requiring the wearing of seat belts by all drivers and passengers, with the exception of children under five years of age, people with medical problems, and people whose work requires them to get in and out of a motor vehicle frequently and whose vehicle travels at a speed not exceeding 40 kph. Highway speed limits were reduced in Feb 1976: previous 70 mph limits (110 kph) were changed to 60 mph (100 kph) and 60 mph limits to 50 mph (80 kph), to 55 mph (90 kph), or left unchanged. Data were compiled on patients treated at selected hospitals in Ontario for injuries sustained in motor vehicle accidents during 1975 and 1976. Compared to 1975, the motor vehicle fatalities in 1976 were 16.1% lower, the number of persons injured 13.7% lower, and the number of hospitalized victims 16.1% lower. The cost of active treatment for hospitalized persons (inpatients and outpatients) decreased by 10.7%. The number of persons with minor injuries declined by 13.0%, the moderate to severe injuries by 14.5%. The average acute hospital stay for patients increased from 11.6 to 12.9 days. The average cost of treatment for victims who reported having worn seat belts was $228, while treatment for victims without seat belts had an average cost of $419. Pedestrians and cyclists incurred average costs of $693 and $498, respectively.

RUNAWAY TRUCK RAMPS ARE SAVING LIVES AND REDUCING DAMAGE

The basic EERRHV (Emergency Escape Ramps for Runaway Heavy Vehicles) types used in the U.S. today are described (gravity ramp, arrester bed, and combination of the two). Positive points of the gravity ramp include: no need for special equipment to remove truck from ramp, minimal routine maintenance, and no impairment by adverse weather. This type of ramp is usually expensive because it must be long enough to dissipate the forward energy of the truck. The arrester bed does not need to be nearly as long as a gravity ramp, and the initial cost is lower. The surface does not require a special treatment, and it is easier to locate near the problem area. Once the vehicle is stopped, it will not roll back, and very little damage is done to the vehicle, although it sometimes takes two wreckers to pull out a tractor-trailer. The ramp surface must be redressed after use, and snow and freezing rain may cause minimal problems. An arrester bed should be wide enough to accommodate more than one vehicle. It is emphasized that no one type or style of runaway ramp is feasible in all situations; each location and physical condition must be considered individually. The success of an EERRHV involves informing the motoring public of ramp function and purpose, and installing signs to inform the driver of ramp location. It is concluded that the use of runaway truck ramps and brake check areas, along with truckers' awareness of the potential dangers of runaway vehicles, may well be the most cost-effective and rational alternatives for minimizing steep grade hazards. Research is needed to obtain certain critical ramp performance data. There are at present no formal de
or construction criteria for guidance in planning these esse
safety features.

THE PERFORMANCE OF NTS (NIIGATA NEW TRANSPORTATION SYSTEM) VEHICLE STEERING CONTROL SYSTEM. A STUDY

A mathematical model was devised to predict the steering performance of an automated guideway system vehicle, especially the effect of some design parameters on lateral motion. It was found that although the clearance between guide wheels and guidewall reduces steering control stability and causes oscillatory lateral motion, this motion is restrained by a connecting rod between the front and rear steering linkages when the steering control gains are chosen appropriately. The mathematical model does not include other degrees of freedom (roll); the vehicle speed is assumed to be constant; and a simplified steering linkage is assumed. Fair agreement was observed between the model calculations and experimental results. The automated guideway transit system is under construction in Osaka City, Japan.

AUTOMATIC CAR-FOLLOWING--A STUDY OF POSSIBLE CONTROLLERS

A class of linear controllers is considered to determine their relative suitability for maintaining longitudinal separation between individual vehicles on an automatic highway. A modified controller using forward- and backward-looking sensors is examined, using a transmission line analogy. Stability concepts are defined and clarified, and characteristics of a well-behaved system are outlined: local stability, car-following stability for at least some low frequency range of disturbance, small separation of cars (for high capacity), reasonable vehicle performance demand, and smooth acceleration/deceleration. It is concluded that the best solution to the longitudinal separation problem lies somewhere in complexity between the modified controller with equal forward and backward gains and the Levine-Athans controller, which regulates each car's acceleration based on information on the states of all cars in the train.

AUTOMATIC LONGITUDINAL CONTROL OF HIGHWAY VEHICLES

The requirements of automatic control of vehicles on expressways are stated and the design of a system to meet the requirements is described. The system is based on control by equipment (computers) carried by the vehicles responding to information as to the positions and speeds of surrounding vehicles transmitted to the controlled vehicle through road circuits. A suggested design for these circuits is described. A method for automatic lane-changing is described and the problem of compatibility of automatic and manually-controlled vehicles using the same lanes is discussed.

TESTING A PROTOTYPE INDUCTIVE POWER COUPLING FOR AN ELECTRIC HIGHWAY SYSTEM

A Dual Mode Electric Transportation system is under development in which energy is electromagnetically transferred from a powered roadway to moving vehicles without mechanical contact. Energy from the roadway can be used for high-speed, long-range travel, and for replenishing energy stored in the vehicle in batteries or flywheels. The stored energy is then available for short-range travel off the powered highway network. A static prototype of the inductive power coupling was built and tested. Power transfer was demonstrated to conform to the models developed in an earlier phase of the project. The prototype was used to study the power of the coupling mechanism and resulting design improvements were incorporated. Tests of properties of the coupling included electrical characterization of the prototype equipment, measurements of the magnetic force between power source and pickup, measurements of coupled power vs. pickup airgap and offset, measurements of magnetic flux in and around the prototype, and measurements of thermal effects induced by coupled power. The tests resulted in several design improvements which were incorporated into the coupling design. Results from the power coupling study were used to aid in the design of the dynamic prototype, in which a 50 m powered test track and electric car with power pickup will be tested.

AUTOMATED CONTROL OF GUIDEWAY TRANSIT VEHICLES

An overview of the control structure for automated people mover systems is presented, and attention is focused on individual vehicle longitudinal and lateral control. A longitudinal and lateral control system which utilizes a fixed guideway reference system was designed, tested, and developed. The fixed

best copy available

guideway reference system is comprised of guideway-mounted measurement markers and an inductive communication link which provides the means for vehicle state error measurement and control. Vehicle status information and longitudinal commands are transmitted to/from the wayside via the inductive link. Measurements of the electromagnetic field surrounding the communication link are used to obtain estimates of vehicle lateral position error with respect to a prescribed path. These vehicle state error measurements are processed by an on-board vehicle computer, and the proper longitudinal and lateral control commands are generated and applied to the appropriate control equipment to effect the necessary longitudinal and lateral control responses. The following preliminary conclusions are drawn. Using the approach described, specific vehicle dynamics data can be used to provide a good estimate of potential wire following lateral control performance. Lateral paths requiring vehicle yaw acceleration provide the most severe input to a wire-following vehicle. Good longitudinal control accuracy and ride comfort are inversely related. Although analytical predictions of longitudinal control accuracy are useful, final control parameter value selection requires actual hardware testing to select a level of accuracy consistent with ride comfort requirements.

ELECTRONIC CONTROL UNIT FOR PASSENGER CAR ANTISKID

The Bosch ABS antiskid system is described, which incorporates modern electronics technologies. Two wheel speed sensors measure the angular velocity of the front wheels. In order to minimize brake force differences of the rear axle on roadways with split coefficients, a common control for the rear wheels was chosen. The hydraulic unit comprises three (for front-rear brake system) or four (for diagonal brake system) novel solenoid valves and a return pump driven by an electric motor. Brake pressure can be raised in a steady or stepwise way, held at a constant level or decreased. The electronic unit is mainly digital, with a few integrated circuits. The antiskid system comprises many sophisticated functions which result in high circuit complexity. The digital design allows for a greater integration than the analog design. To ensure optimal system safety, the main components of the system are checked for proper functioning prior to driving the vehicle. En route, the main system components are continuously monitored. The overall antiskid system is switched off once a critical defect has been detected. In that case the normal brake system is available and a warning lamp indicates to the driver that the antiskid system is not functioning. Two German automobile manufacturers are introducing the system and others are expected to follow.

MICROWAVE AUTOMATIC VEHICLE IDENTIFICATION (AVI) SYSTEM

A microwave automatic vehicle identification (AVI) system is described which utilizes piezoelectric resonators to encode identification numbers of a vehicle and a microwave carrier to transmit information between the transponder and the interrogator system. Elimination of any active elements in the transponder and miniaturization, coupled with the lowering of the transmitted microwave power, are epoch-making advances realized in this system. The system structure, the operational principles of the interrogator and transponder, and the transponder circuit structure are described, as well as an overhead type AVI system which has practical application for toll roads and highways. Other applications include ID cards, electronic locks, and the like, for which the totally passive, compact, and lightweight transponder can be regarded as most suitable.

MICROPROCESSOR-BASED SYSTEM FOR ROLL-DOWN AND ACCELERATION TESTS

A microprocessor-based, road-test system for measuring and recording rolldown and acceleration data was designed and built. The system provides for rapid testing of vehicles, can be operated by a single individual, and allows detailed data acquisition when required. Digital data storage and output capability allows direct exchange of data with other computers or calculators for data analysis and reduction. System inputs are distance from a fifth wheel, and elapsed time. The microcomputer system records time to the nearest 0.01 sec, distance to the nearest ft, and calculates velocity to the nearest 0.1 mph. Data can be stored at specified time, distance, and velocity intervals. Current time, distance, and velocity are displayed on a liquid crystal display panel. A printing calculator prints a summary of the run. Detailed data is stored in RAM (random access memory) and is output to magnetic tape at the end of the run. The tapes are used to obtain plots and as input for data reduction programs that calculate rolling friction and aerodynamic drag. The road-test system was first used in a fuel-cell powered vehicle program which required characterization of the performance of a number of vehicles. Since it is microprocessor-based, the system is also intended to be used as an expanded data acquisition system for a fuel-cell powered vehicle. The first time the system was used, 12 vehicles were tested for three days. A total of 103 rolldown and 13 quarter mile acceleration runs were made. In most of the tests one person drove the vehicle and operated the road-test system. Data were saved on tape at 1 sec and 1 mph intervals.

HIGH QUANTITY, LOW COST, HIGH ENVIRONMENT AUTOMOTIVE TRANSDUCERS, A NEW BREED FOR USE IN ADVANCED AUTOMOTIVE ELECTRONIC SYSTEMS

The use of transducers in automotive electronic control systems (i.e. electronic fuel injection) is described, as well as high-volume production techniques in manufacturing transducers. Categories of transducer use include emission control (with pressure transducers and speed sensors); antiskid, or anti-wheel-lock (with speed sensors); and diagnostics, such as monitoring ignition timing, measuring wear in brakes, steering columns, and shock absorbers, and monitoring of various conditions in frame and transmission (with speed sensors, linear and angular position sensors, pressure sensors, and acceleration sensors). Problems involving transducer specifications include performance under extreme temperatures, or separation of electronics from the transducer; costs; and consistency in performance. The linear variable differential transformer and the proximity transducer are described, as well as the development of electronic circuitry to interface directly with a digital computer. Future areas of transducer development are outlined.

HIGH CAPACITY AUTOMOBILE TELEPHONE SYSTEM

The main features are outlined of the 800 MHz High Capacity Automobile Telephone System for public mobile services, now under construction in the Tokyo metropolitan area. The major features of this system include high capacity (100,000 subscribers can be accommodated in the same service area); efficient utilization of frequency spectrum in the 800 MHz band (introduction of small radio zone structure (cellular system) for reuse of the same frequency in radio zones with adequate distance for avoiding co-channel interference, the increase in the number of channels commonly used by each mobile unit within a radio zone, and reduced occupied bandwidth of radio channels); and fully automatic exchange for a nationwide mobile service. The following advanced techniques were introduced: vehicle location registration technique, by which a switching equipment memorizes the newest location (paging area) of each mobile subscriber; call hand off technique, which enables continuous conversation when a vehicle moves from one radio zone to another during a call; and multi-channel access control with two kinds of control channels (paging channel and access channel). Improvements being developed to enrich and expand the service are listed.

AN ACCIDENT-SEVERITY ANALYSIS FOR A UNIFORM-SPACING HEADWAY POLICY

In order to assess the severity of accidents resulting from high-density traffic on an automated highway system, a methodology is presented to ascertain the severity of one especially critical type of accident: a multi-vehicle collision resulting from the emergency braking of a platoon of automatically-controlled, closely-spaced vehicles. This methodology includes the specification of a collision model, which was based on reported crash-testing results, the selection of an accident severity measure, consideration of a corresponding cost function, and a sensitivity analysis to determine those parameters which most heavily impinge on accident severity and/or cost. The accident severity measurement was simplified because sufficient accident data were not available to justify a more meaningful and complex choice. Necessary data for measuring accident cost in dollars were also lacking, but a qualitative measure of the effects of key parameters on accident severity is provided. The utility of the developed methodology was demonstrated by applying it to three accident scenarios, and resulted in the following observations. "A-1" (the lead-vehicle deceleration to which the platoon can safely respond) should be as large as possible. Accident severity was, in some cases, greatly increased when a serial reaction delay (rather than a single parallel delay) was present. A moderate increase in the parallel reaction delay resulted in a relatively small change in accident severity. Accident severity was very sensitive to decreases in the deceleration capabilities of the following vehicles. Such results, especially in a quantified form, provide useful measures of the effect of making different policy choices.

DETERMINATION OF VEHICLE ROLLING RESISTANCE AND AERODYNAMIC DRAG

Rolling resistance and aerodynamic drag were determined to estimate the retarding forces on a vehicle. These forces are especially important in determining power requirements for an electric vehicle. Rolldown tests were conducted on a number of vehicles on a level drag strip in two directions, with a fifth wheel feeding 100 pulses/ft into a microcomputer system. Time was measured to the nearest 0.01 sec, velocity to the nearest 0.1 mph, and distance to the nearest ft. Velocity and distance were recorded in read/write memory at one-sec intervals, and stored on magnetic tape which was used to plot routines, and for data reduction programs. In order to assure valid data, vehicles were warmed up and weighed, tire pressures checked, windows rolled up, and wind velocity, air temperature and air pressure were measured. It was found that vibration and bounce of the fifth wheel seriously affected the coastdown tests, and efforts were made to minimize these effects. Equations used in calculating rolling resistance and aerodynamic drag are presented, and data analysis techniques are described.

AN APPLICATION OF EQUATION ERROR IDENTIFICATION TECHNIQUES TO THE PROBLEM OF VEHICULAR DRAG PARAMETER DETERMINATION

A system identification technique is applied to a vehicle undergoing a coastdown test for the determination of the aerodynamic and rolling resistance of the vehicle. The method identifies these characteristics without imposing any assumption on their relationships with velocity. the results of the identification technique show close accuracy with respect to actual vehicle values. This technique can be used in either off-line applications by means of recorded data or in on-line applications. By making use of a small computer installed on board the vehicle, instantaneous values of drag and rolling resistance or their total can be obtained in real time as the vehicle operates in any straight and level roadway condition.

IGNITION NOISE OF FOREIGN AND DOMESTIC VEHICLES IN USE IN THE UNITED STATES

Electromagnetic noise from the ignition systems of more than 11,000 individual vehicles in service in the U.S. in mid-1977 was measured at 50 MHz and 153 MHz. The following similarities and differences are shown between the ignition noise levels of several vehicle sets: the difference in ignition noise levels from the noisiest to the quietest individual vehicles of any selected set is as great as 50 dB or more; the difference from one vehicle set to another is generally quite small; all the vehicle sets examined contained some very noisy vehicles; the greatest difference among vehicle sets was found by classifying them by vehicle type; foreign vehicles are only slightly noisier than U.S. vehicles; and age (or model year) differences are more apparent in U.S. vehicles than in foreign, older vehicle groups being noisier than groups of later models.

PERFORMING SAE (SOCIETY OF AUTOMOTIVE ENGINEERS) J551D RADIO INTERFERENCE TESTING OF AUTOMOTIVE VEHICLES USING THE PROGRAMMED AUTOMATIC SPECTRUM ANALYZER

The use of the new computer controlled automatic spectrum analyzer brings "instant" analysis to SAE J551d radio interference measurements, enabling manufacturers of automotive products to reduce radio interference levels economically. A brief history of automotive radio frequency (RF) interference and the beginnings of SAE J551 are presented. Measurement techniques are described, beginning with manual recordings on an individual frequency basis, then advancing to semi-automatic X-Y plotting on an octave-by-octave basis, to automatic X-Y plotting, and finally to the computerized automatic spectrum analyzer with finalized semi-log charts ready for report presentation. Various RF measurement methods are compared to show the advantages and disadvantages of each. Among the big advantages of the computerized spectrum analyzer are increased reliability and the presentation of the data in a conventional format, easy to understand by management as well as by engineers. Reduction of total time from the taking of data to final presentation is in the order of tenfold over X-Y plotting, and one hundredfold or more over manual measurements.

MULTIPROCESSOR SYSTEM FOR DEVELOPING CONTROL STRATEGIES OF CAR ENGINES

A tightly connected multimicroprocessor computer system is described, with reduced overhead due to shared resources by using separate modules and a hardware arbiter (access) control system. Use of programmable peripherals permits a large number of input/output lines, giving easy interface reconfigurability. Use of the system in developing engine control strategies is outlined. Complex interface with actuators and sensors is managed by an interrupt driven software, which takes advantage of the parallel structure to enable synchronization with engine timing. Hardware modularity and distribution of computing load allow a high degree of run time interaction between user and control system. System compactness is such that the same controller can be used for different steps of experimentation as required.

THE SEATED BUS PASSENGER--A REVIEW

Seven aspects related to the ergonomics of the bus passenger are discussed: approach to the seat, access to the seat, dimensional aspects of the seat, seat shape, seating layout and configuration, seat strength (structural stiffness under impact), and dynamic aspects of travel comfort. A two-phase study was undertaken by Leyland Truck and Bus on all aspects of the bus travel environment, especially the problems encountered by the elderly. Many of the seven ergonomic factors are interrelated, but studies performed on moving to the seats and dynamic travel comfort have identified the importance of vehicle acceleration and jerk. Comfort, stability, and safety of all bus passengers are affected by acceleration conditions in the vehicle. Careful design of seat structure and detailed analysis of accident data have shown that, under accident conditions, passenger injuries can be minimized. Different requirements of various categories of the traveling population have been identified in rig studies. Study results and application of appropriate anthropometric data have resulted in optimum use of the space available on the vehicle, this being reflected in recommendations for seat layout, shape, and dimensioning. Much of this work has been incorporated in the design and development of a new double-deck bus, the Leyland Titan.

JAPANESE GOVERNMENT WHITE PAPER ON TRANSPORTATION SAFETY. 1979 ED.

A comprehensive picture of the traffic accident situation in Japan (primarily in 1978) is given. The report includes results of studies of traffic safety measures implemented in fiscal year 1978, and plans for implementation of such measures in fiscal year 1979. Road, railway, marine, and aviation accidents and their countermeasures are discussed separately. In highway accidents, there were 8783 fatalities in 1978, a 1.8% decrease from 1977 and a 47.6% decrease from the peak year of 1970 when there were 16,765 fatalities. The annual fatalities have been steadily decreasing for the eight years since 1971. On the other hand, the number of persons injured in traffic accidents increased slightly to 594,116, a 0.2% increase over 1977. There are tremendous regional differences in traffic fatality rates. Pedestrian and bicyclist deaths made up nearly one-half of the total fatalities; the number of people killed while riding two-wheeled vehicles is on the increase. There were increases in traffic accidents among the 7- to 15-year-old group and the elderly (over 70). A high percentage of fatal accidents were associated with drunken driving, speeding, and driving without a license. Train accident fatalities and injuries showed a decrease. The number of ship accidents decreased by 12 from 1977, but there was an increase of 15 dead or missing. There were the same number of air traffic accidents in both 1977 and 1978, with 17 less fatalities but nine more injured persons in 1978.

STATISTICS '78 OF ROAD TRAFFIC ACCIDENTS IN JAPAN

Statistical data are tabulated on the road traffic situation in Japan from 1946 through 1978: vehicle registrations, population, driver's license holders, total road length, and motor vehicle km traveled (VKMT). Traffic accident historical trends are indicated in tables on accidents and casualties; fatalities by prior movement of road user; casualties per 100 million VKMT, and per number of vehicles and population; comparison of police and Ministry of Welfare statistics on fatalities; and accidents by day and night. For 1978, separate sections provide tabulated data on traffic accidents, fatal accidents, casualties, child casualties, and traffic accidents on expressways. Statistical information is also tabulated for various years concerning traffic violations, traffic regulations and controls, driver's license holders, company safe-driving supervisors and administrators, and road conditions.

FREEWAY TRAFFIC MANAGEMENT. FINAL REPORT

An overview is provided of proven traffic control techniques for reducing congestion and improving operations on urban freeways. These techniques will be of interest to highway administrators, legislators, and other public officials. Alternative measures are described that are being used effectively in various cities to deal with the compound problem of ever-increasing traffic demand on existing freeways and de-emphasis on providing new facilities. Operational and safety problems typical to an urban freeway corridor, a range of options for dealing with these problems, and guidelines for implementing and operating freeway control systems are described. The discussion is based on previous research, actual experience from operating freeway control systems in various parts of the U.S., and numerous interviews with individuals having responsibility for those systems. Included are abstracts of six major reports on freeway traffic management, and a selected bibliography.

THE USE OF CHILD PASSENGER SAFETY DEVICES IN TENNESSEE

An evaluation was made of the combined impact of the Tennessee child restraint law and its associated promotional campaign on restraint usage rates, including comparisons between users and nonusers. On 1 Jan 1978, Tennessee enacted a law establishing safety requirements for child passengers under four years of age. A public information and education (PI and E) campaign was simultaneously initiated which called for distribution of brochures and posters in pediatricians' offices, hospitals, etc., as well as an extensive mass media effort. The distribution program was implemented and evaluated in five target areas, the mass media program in one target area. Baseline data were obtained just prior to law and campaign implementation; six months later, parallel surveys were conducted. It was found that the combined law and distribution campaign was effective in increasing restraint usage rates, with the mass media program assuring even higher usage rates. Usage was found to be associated with child's age, all socioeconomic variables (e.g. family income and education level), other demographic and vehicle data, and the wearing of seat belts. A market segmentation strategy for future PI and E campaigns is proposed.

LEARNING IS FUN WITH THE NATIONAL SAFETY COUNCIL'S CHILD SAFETY CLUB

The National Safety Council's Child Safety Club teaches children, ages three through five, how to stay safe at home, at play, and in traffic, through games they can play with adults. During this age period, a child receives five books at six-month intervals. Each book builds on previous lessons, but focuses on the new hazards the child encounters as his horizons widen. Safety activities include puzzles, quizzes, and pop-outs. Each book offers interesting information about traffic, home, and recreational safety which the adult discusses with the child. A picture page opposite each page of text illustrates a major safety topic. Some of the pictures contain "do-it-together" activities; real-life practice experiences are presented at the conclusion of each topic. Traffic lessons cover safe playing outdoors (never play in the street and walk only on the sidewalk), and using a child safety seat (and a seat belt for the adult). Children under three may be enrolled any time after birth, but will not receive the first book until their third birthday. Child Safety Club memberships are $15 for the complete package, including mailing costs. A special rate of $13.50 is offered to organizations who sell 50 or more memberships, providing them with a small profit when they sell the memberships at the regular price.

THE GREAT ARKANSAS MOTORCYCLE HELMET LAW FIGHT

The public information and education program manager for the Arkansas Hwy. Safety Prog. discusses his successful experience in coordinating the fight to preserve his state's motorcycle helmet law. The "secrets" of this success are discussed, with the pitfalls encountered, and some methods to avoid them. In preparing for such an effort, it is recommended that a good "inside person" (preferably a legal aide working for the legislative council) be consulted. The value of doing research is emphasized, and acknowledgement is given to the special assistant for public information and community support at the National Hwy. Traffic Safety Administration. Putting too much stock in the predictability of the opposition's strategy is not advised. Private visits are recommended with legislators to explain one's position, particularly with those serving on committees most likely to consider the repeal or modification bill. Other prehearing steps include: obtaining public opinion data, enlisting the aid of high-placed officials (if popular with the legislature), getting the support of professional and civic organizations, assembling a balanced group of speakers to testify, and rehearsing the presentation. Contact with the American Civil Liberties Union is also suggested. Suggestions for the hearing itself include filling the room with supporters, letting the opposition speak first, using notes rather than prepared speeches, keeping statements short, avoiding redundancy, being economical with statistics, being alert to possible manipulation of data by opposition, and not letting the opposition claim that they are representative of all motorcyclists nor letting them divert attention from helmets to motorcycle rider education.

BLOOD ALCOHOL LEVEL DISCRIMINATION BY ALCOHOLICS: THE ROLE OF INTERNAL AND EXTERNAL CUES

Two groups of four chronic alcoholic subjects lived in Rutgers' Alcohol Behavior Res. Lab. for separate two-week periods, during which time they were taught to attend either to internal or to external cues to blood alcohol level (BAL). During a single training session, subjects received feedback on actual BAL following each of their BAL estimates. During pretraining and posttraining sessions, assessments of BAL estimation accuracy were obtained in the absence of feedback. Prior to training, both groups of alcoholics were equally inaccurate in estimating BAL. During training, when accurate BAL feedback was provided, estimation accuracy increased significantly for both groups. Once feedback was removed during the posttraining test session, only externally trained (via a programmed learning booklet) subjects maintained the ability to estimate BAL accurately. It is concluded that unlike the nonalcoholic subjects studied by Huber, Karlin, and Nathan, the alcoholic subjects of this research did not learn to discriminate BAL on the basis of internal feelings and sensations nearly as well as when they referred to external cues.

SCALING PERCEIVED DISTANCE ALONG A ROAD

The relationship between perceived and real distance along a road was investigated using the method of fractionation in a field experiment and two laboratory experiments. In each case, data were well fitted by a modified form of Stevens' power law. Although one laboratory experiment failed to reproduce field study results, when distance stimuli were improved by using ordinary cars instead of lights to define standard distances, laboratory results were closer to those obtained in the field.

HIGH CERVICAL SPINE AND CRANIOCERVICAL JUNCTION INJURIES IN FATAL TRAFFIC ACCIDENTS: A RADIOLOGICAL STUDY

Postmortem radiographic examination records of 312 victims of fatal traffic accidents were analyzed with respect to injuries to the cervical spine. One-third of the subjects were pedestrians struck by a vehicle; the others were occupants of various motor vehicles and a few bicyclists or motorcyclists. Twenty-four percent of the victims radiographically demonstrated neck injuries. Most fractures and dislocations in this group were found to involve the craniocervical junction and the upper two cervical segments. Over one-half were flexion injuries; one-fifth were caused predominantly by extension; the mechanism of one-fourth of the injuries could not be determined, although they were probably due to lateral forces or a combination of several vectors. Flexion and extension views were particularly helpful in demonstrating the instability of many injuries. The high incidence of upper cervical and craniocervical junction injuries emphasizes the importance of continued research into safety devices for protection in this vital area. Seat belts, particularly the harness type, and head restraints would appear to afford protection to the torso and tend to reduce extension injuries of the neck, although these devices afford little protection against flexion injuries of the upper cervical spine. It appears that the air bag should help in reducing this type of trauma.

AN EXPLORATORY STUDY OF ATTITUDES AND OBSERVATIONS ON CHILD PROTECTION IN MOTOR VEHICLES

On seven weekdays in Mar-Apr 1979, drivers were interviewed and restraint use observed in 122 vehicles being used to deliver and pick up children at seven nursery schools and daycare centers in Baltimore County, Maryland. The vehicles carried 151 children; 58% were age three to four and 5.5% were younger (the median age being four). Only 15 children (10%) were restrained, primarily with lap belts. The majority of the children (54%) were traveling in the front compartment of the vehicle. Of the 131 adults in the vehicles (73% being women), only 11 (9%) were wearing seat belts. Safety belt use by adults was most common in the highest socioeconomic groups; among children, this correlation was less marked. Of the 122 drivers interviewed, 81 believed that restraint use should be required by law for children, 21 disagreed, and 20 were undecided. Seventy-eight percent said they would restrain their children and 84% would restrain themselves if they were required by law. Fifty-five percent of the drivers said they did not have problems with the use of seat belts or child seats to restrain their children. The most frequent complaint (8%) was that the shoulder portion of the combined lap-shoulder belt was not designed for children, rubbed against the neck, and/or was dangerous. Child restraint legislation is recommended, as well as better public information for parents, and consideration of acceptability and convenience by vehicle and safety device manufacturers.

IMPACT OF MOTORCYCLE HELMET LAW REPEAL

Comparable periods before and after repeal of the Kansas motorcycle helmet law, effective 1 Jul 1976, were studied in terms of number of crashes, number of motorcycle registrations, injury severity, rate of injury, and number of fatalities. It was found that there was a significant difference in the fatality and injury rates based on helmet usage. During the 1975 period, six motorcycle fatalities occurred; during the 1976 period, there were 11 fatalities. When comparing fatalities to motorcycle registrations, there was a 95% increase in the fatality rate between law and repeal periods. The crude death rate for those not wearing helmets was 333% higher than that for helmeted riders. Between 1975 and 1976, there was an increase of 17% in the crude rate for general body injuries, an 8% increase in rate of injuries to the extremities, and a 51% increase in the crude rate of head injuries. The injury rate for the nonhelmeted population was 25% greater than for persons with helmets. The former had a 106% higher rate of head injuries, and a 67% higher mean injury severity score. The use of helmets was significantly higher during the period when the helmet legislation was in effect. It can be concluded that a mandatory helmet use law significantly reduces motorcycle crash-related death and serious injury because more drivers and passengers wear helmets when required by law. The status of state helmet-use laws is tabulated in a separate section.

GASOHOL. A TECHNICAL MEMORANDUM

The technical and nontechnical (economic, environmental, and social) issues surrounding the development of gasohol (10% ethanol, 90% unleaded gasoline) are addressed. The resource base, production technologies, and economics of gasohol, and its use as a transportation fuel are discussed. Also considered are the environmental problems and benefits of producing and using gasohol, and the social and institutional issues concerning use of agricultural products for energy. Current Federal gasohol programs and policies are summarized, but policy options are not analyzed. Estimates are provided of how much gasohol can be used at what cost, and of the long-term prospects of ethanol production. Major areas for research and development are identified (feedstocks, conversion and end use).

15 KWE (NOMINAL) SOLAR THERMAL ELECTRIC POWER CONVERSION CONCEPT DEFINITION STUDY--STEAM RANKINE TURBINE SYSTEM. FINAL REPORT

A study was performed to define the performance and cost characteristics of a solar-powered, steam Rankine turbine system located at the focal point of a solar concentrator. A two-stage re-entry turbine with reheat between stages was selected for the conceptual design. This system has an efficiency of 27% at a turbine inlet temperature of 732 degrees C (1350 degrees F) where system efficiency is defined as 60 Hz electrical output divided by absorbed thermal input in the working fluid, Toluene. Mass production system costs would be approximately $364/kw; operation and maintenance costs, $0.0078/kwh. The principal conclusion of the study is that relatively high steam turbine Rankine system efficiencies are achievable with good off-design performance; but advancement of the state of the art, in the form of turbine interstage sealing techniques, is required to achieve this performance.

15 KWE (NOMINAL) SOLAR THERMAL-ELECTRIC POWER CONVERSION CONCEPT DEFINITION STUDY--STEAM RANKINE RECIPROCATOR SYSTEM. FINAL REPORT

A study was undertaken to identify steam Rankine power conversion concepts with the potential for significantly improved efficiency at the lower power levels associated with point focusing distributed solar systems. Parametric studies led to the selection of 677 degree C (1250 degrees F) and 17.2 x 10 to the 6th power N/sq m (2500 psi) as maximum steam inlet temperature and pressure. A conceptual design of a 3600 rpm reciprocation expander was developed for maximum thermal input power of 80 kW. The conceptual design covered two engine configurations; a single-cylinder design for simple cycle operation and a two-cylinder design for reheat cycle operation. The reheat expander contains a high-pressure cylinder and a low-pressure cylinder with steam being reheated to the initial inlet temperature after expansion in the high pressure cylinder. Power generation is accomplished with a three-phase induction motor coupled directly to the expander and connected electrically to the public utility power grid. The expander, generator, water pump and control system weigh 297 kg (654 lb) and are dish-mounted. The steam condenser, water tank and accessory pumps are ground-based. Maximum heat engine efficiency is 33%; maximum power conversion efficiency is 30%. Total cost is $3307 or $138 per kW of maximum power output.

ARKANSAS MOTORISTS: THE 55 MPH SPEED LIMIT AND SAFETY DEVICES

A statewide survey is reported of Arkansas motorists' perceptions, attitudes, and behavior patterns regarding the fifty-five miles per hour speed limit, and their usage patterns and attitudes concerning safety belts, child restraint systems, air bags, and motorcycle helmets. It was found that about one-half of the motorists exceed the speed limit, mostly by only ten mph or less, which is apparently considered to be the "effective" speed limit given perceived levels of enforcement. Most motorists recognize the fatality and accident reduction effect of the 55 mph speed limit, and they favor retaining the law for these reasons, not for saving gasoline. It was found that nonuse of safety belts is extremely widespread, not because of major objections to safety belts but because of motorist laziness or thoughtlessness. The same rationale exists for not using child restraint systems, although these systems are used to a somewhat greater extent. A surprisingly large number of motorists are aware of air bags and how they work. The motorists may favor mandatory air bags precisely because they are passive. The respondents were not informed of air bag costs when interviewed. Motorcycle helmets are by far the most widely accepted safety device among Arkansas motorists; they are accepted and supported almost unanimously.

ARKANSAS MOTORISTS: OPINIONS AND ATTITUDES ABOUT DRINKING, DRIVING AND ENFORCEMENT OF RELATED LAWS

A statewide survey is reported of Arkansas motorists' awareness, opinions, and behavior patterns with respect to drinking and driving and the nature and enforcement of laws concerning those activities. Nearly two-thirds of the Arkansans surveyed report never drinking at all. They are generally well-informed of alcohol's effects but unaware of the alcoholic potency of beer and wine. By a three-to-one margin, the drivers are well aware of diminished driving ability after a "few" drinks, but somewhat uninformed about how to become sober. Almost none of the drivers are aware of the true legal meaning of driving while intoxicated (DWI) and most do not know the amount of drinking required to reach the legal limit. They are quite uninformed about DWI consequences. By a three-to-one margin, Arkansans believe the DWI penalties are fair. They are uninformed about available state drinking/driving programs. By a nine-to-one margin, a program of alcohol education in the public schools is favored. Arkansans' media attention patterns are close to national norms, with most radio listening during morning and afternoon commuting periods, and most television viewing during prime time.

METHODS OF EVALUATING THE EFFECT OF AERODYNAMICS ON THE FUEL CONSUMPTION OF COMMERCIAL VEHICLES

Wind tunnel tests, full-scale coastdown tests, and extended road running have been compared as methods of evaluating the effectiveness of devices for reducing the aerodynamic drag of heavy commercial vehicles. Comparing the results of the coastdown tests with an accurately detailed 1/10 scale wind tunnel test, it is concluded that the latter method is the best means of examining basic aerodynamic effects. Coastdown tests are too susceptible to the effect of small variations in experimental conditions to be effective in evaluation. For the fleet operator, the best method is probably a road test comparing the performance of a modified and an unmodified vehicle. In the U.S., such a two-vehicle road test procedure has been recommended by the Regular Common Carrier Conference/Society of Automotive Engineers; details of the Recommended Practice are appended.

M6 RECONSTRUCTION 1976: TWO-WAY TRAFFIC USING NARROW LANES (STAFFORDSHIRE, ENGLAND)

A system of two-way traffic using lanes of substandard width to provide two traffic lanes in each direction on a single three-lane roadway was implemented during the reconstruction of a section of M6 motorway (freeway) in Staffordshire, England during 1976. Despite the reduced lane widths (2.75 m for light vehicles, 3.35 m for heavy vehicles), the capacity and journey-time/flow relations for the site did not differ appreciably from those for standard lanes. Even when the hard shoulder (which was in use as a traffic lane) failed locally under the weight of the heavy vehicles, and the relative positions of the light and heavy vehicles were reversed to reduce the loading on the hard shoulder, the extra maneuvers involved did not appear to affect the performance of the site. Overall, the delays averaged only 270 vehicle-hr/day, and these would have been considerably higher if any other method of operation (segregated contra-flow or two-way operation with standard-width lanes) had been used. The accident rate at the site averaged 35 injury accidents per 100 million vehicle-km, rather less than that experienced in general at other major road construction sites, whether or not narrow lanes were used. The increased accident rate was confined entirely to the daytime accidents. It is concluded that narrow lanes are not specially hazardous.

ALTERNATIVE PRIORITY MARKINGS FOR SAFETY AT SUBURBAN T-JUNCTIONS

A test track experiment was conducted to compare the operational feasibility of four alternative priority markings for urban T-junctions as a preliminary step to a safety evaluation on public roads. The first major/minor road design was conventional, with the stem of the T as the minor road approach. As unconventional layouts, the second and third designs, respectively, had the right arm and the left arm of the head of the T as the minor road approach; the "major" route was defined accordingly to turn on the left or the right shoulder of the T. The fourth design was a small traffic circle with offside priority markings on all approach roads; this is a proven option with traffic and safety benefits. The main objective was to evaluate the turning-priority designs in terms of delay, capacity, and driver response. It was concluded that both unconventional designs would be acceptable to drivers and would not cause traffic engineering problems. The left shoulder layout would be preferable, and several pilot installations of this alternative are recommended prior to a large-scale trial to determine its effect on traffic safety.

"TOWN BEAMS" FOR VEHICLES--EXPERIENCE WITH AN AUTOMATIC HEADLAMP DIMMING SYSTEM

The design and construction are described of an automatic system for controlling the intensity of the low beam headlight according to the quality of the street lighting. Results are reported of large-scale trials of the system installed in Post Office and Police vehicles, with particular attention given to driver acceptability and system reliability. It was found that many drivers were not satisfied with the performance of the automatic system, and the failure rate of the units was found to be unacceptably high. Driver dissatisfaction was the result of "flashing" effects experienced in slow-moving traffic. As it is not possible to modify the units to overcome drivers' objections, it is recommended that the development of the automatic system be discontinued. Work on the "town beam" (dimmed low beam) should concentrate on a manual system which is controlled by the driver.

DEVELOPMENT OF A WET WEATHER SAFETY INDEX. FINAL REPORT (HIGHWAY ACCIDENT PREDICTION AND REDUCTION)

Research was undertaken to develop an efficient way of using traffic and highway characteristics to identify highway segments having a high potential for wet weather accidents and to develop a priority rating scheme for using maintenance funds to maximize accident reduction. The first of two wet weather safety indices developed, WWSIa, is an analytical index based on a number of previous analytical and empirical studies on tire-pavement friction, vehicle handling and stability, potential for hydroplaning, and visibility during periods of rainfall. The index is a site-specific formulation which will enable highway engineers to select appropriate combinations of road surface geometrics, surface textures and skid numbers for the design of road elements, as well as to analyze existing sites. The second, WWSIe, is an empirical formulation based on prediction equations for wet accident rates. The equations were derived by multiple regression techniques from a survey of 60 highway segments in Texas. These segments covered a range of wet accident rates from zero to 40 accidents per year per mile. In general, much higher values of wet accident rates are observed in urban areas than in rural areas. The sensitivity to pavement skid resistance is also much higher in urban than in rural areas.

DRIVER EYE HEIGHT: A FIELD STUDY

A photographic method was used to collect a sample of dynamic observations of driver eye heights for normal driving positions and under normal conditions. Analysis of the sample indicated that driver eye heights for 89% of the compact and smaller passenger cars and 73% of the intermediate and full-size passenger cars were less than the present standard eye height of 3.75 ft used in design and traffic engineering practice in 1975. Only 15% of the driver eye heights were found to be less than 3.75 ft in a 1960 study. It is suggested that presently calculated safe passing sight distances as well as designs of vertical curves may be inadequate and unsafe. No-passing-zone striping and design of roadway vertical and horizontal curves should consider such reduced driver eye height standards. The 15th percentile value of 3.5 ft found in this study would provide a suitable standard.

CALIFORNIA'S SAFETY EFFORTS--PAST AND PRESENT (HIGHWAY CONSTRUCTION AND MAINTENANCE ZONES)

Recent efforts by the California Department of Transportation (Caltrans) to improve the safety of motorists, pedestrians and workers in highway construction/maintenance zones are described, as well as the current planning effort to provide safety training about these sites on a statewide basis. A July 1965 study by Caltrans of accident rates within construction zones resulted in a number of recommended practices now recognized nationally: design of zone detours for the speeds vehicles will travel, avoidance of sudden changes in geometric standards or speed limits, engineering of the traffic way to the highest practicable standards, and removal of superseded pavement markings. A 1970 study of these practices proved their accident reduction effect. In 1967 and 1968, highway safety seminars were conducted for Caltrans and city, county, and Federal employees on providing safer facilities for travelers and maintenance workers. A 1974 study identified work functions and related tasks which are most hazardous to maintenance and construction personnel. Caltrans has continued to conduct "before" and "during" construction zone accident studies on a sample of projects. In July 1977 and in May and July 1978, the Federal Highway Administration's (FHWA) course, "Traffic Control for Street and Highway Construction and Maintenance Operations," was presented to Caltrans and local agencies. By July 1978, a technical advisory committee representative of the intended audience had been formed to develop a training program on construction/maintenance zone construction safety. In December 1978, instructors attended an FHWA "Training for the Trainers" course, and in March 1979, the first of 140 two-day "Safety through Construction and Maintenance Zones" training sessions is to be presented in California. The course, to be given under the sponsorship of the University of California's Institute of Transportation Studies, has been designed for an estimated 4000 Caltrans personnel, and city, county, contractor, and public utility company employees.

MOTORIST INFORMATION NEEDS IN WORK ZONES

As one of the underlying concepts of Positive Guidance, the decision sight distance concept is discussed. Essentially, it presents a model of the driver's needs in coping with a hazard ahead by defining hazard-avoidance subtasks and their time frames, so that displayed information may allow time for effective performance in negotiating the hazard. The decision sight distance concept, as applied to a work zone, is illustrated through a hazard avoidance model. The subareas of a construction zone which provide different information to the driver, or "information handling zones", are depicted. A flow chart combines the information handling zones, driver tasks/actions required in each, decision sight distance processing times, information required, and display options (using a one lane closure situation on an open highway as the example). The proper presentation of display information for the effective, safe negotiation of a work zone is discussed. The importance is emphasized of the total impression conveyed by all work zone elements. The system should present a consistent, clear, credible image so that the driver knows exactly what to do and is given enough time to do it. The motorist's most important work zone needs are: adequate relevant advance information, channelizing and delineation of a clear path through the work zone, use of devices and markings consistent with driver expectancies, adequate maintenance of work zone information sources, and credible information systems.

HIGHWAY LIABILITY--A REVIEW OF WORKZONE ACCIDENT CASES

Four liability lawsuits are reviewed concerning work zone traffic accidents. The first accident occurred at a bridge removal site in which the driver was critically injured and his passenger killed after the vehicle failed to make a turn and struck a crane. Suits were filed against the bridge contractor, alleging failure to adequately and appropriately provide warning to the traveling public. The contractor was found guilty of negligence because of alleged oversigning 500 ft prior to the point of "detour" and failure to reflectorize barrels and barricades adequately at a run-around. The jury also found the driver guilty of contributory negligence, which barred recovery in that particular state. The second case involved a head-on collision (resulting in very severe injuries) at a median crossover, with two-lane, two-way traffic proceeding on one side of a four-lane divided roadway due to repair and bridge construction on the remaining two lanes. This accident was found related to inadequate traffic controls at the site. The contractor made an out-of-court settlement with the plaintiff. The third case involved a resurfacing project on a two-lane rural highway. Four curves on the section were superelevated, and before the shoulders were brought up to grade, a pickup truck was apparently forced off the road and overturned. A passenger in the truck who was ejected is now a quadriplegic. The contractor settled his portion of the litigation out of court. However trial court ruled that the state could not contract away its responsibility for providing and maintaining a safe roadway. The award was nearly $1,000,000. The final case involved an accident at a very sharp crossover area on a four-lane divided highway. The Dept. of Highways was found negligent in the design of the crossover and provision of adequate warning and guidance to the motorist.

THE DELAY TO VEHICLES AND PEDESTRIANS AT SIGNALIZED INTERSECTIONS

The likely paths of pedestrians at signalized intersections in Brisbane, Australia are considered where the method of control is a shared phase with motor vehicles or is an exclusive pedestrian phase for any direction of crossing. The four types of pedestrian control at intersections include simultaneous release of pedestrians and turning vehicles, late or early release of pedestrians, and exclusive pedestrian phases or "scramble" (i.e. pedestrians crossing directly or diagonally). The last type of control is used in Australia. Equations are provided for calculating the delays in both modes of pedestrian crossing and the Australian calculation method for determining signal timing plans is presented. A simple numerical example shows that whatever the method of pedestrian control, standard or scramble, the signal cycle time used in Australia should be reduced to lessen pedestrian delay at signalized intersections. It is shown that there is a considerable increase in vehicle and pedestrian delay with scramble crossing.

THE FUEL-SAVING SHAPE OF CARS TO COME

CAFE (corporate average fuel economy standards) is the main factor at work in reshaping U.S. cars for the future. In the 1980's, American-made cars will be made smaller (to meet fuel economy standards), but prices will rise at about the same rate as inflation if there are no Federal anti-inflation guidelines. New braking, steering, and suspension designs will provide quicker stops, more precise steering, and less roll and sway in corners. In 1983, the compact car will be the size most produced. Front-wheel drive will be more prominent as a weight (and gas) saving measure. Further weight reductions will be achieved by the use of more aluminum and plastic to replace steel. More cars will be driven by four- and six-cylinder engines equipped with turbochargers. Electronic engine controls will set spark timing for fuel economy and lower emissions by adjusting the air-fuel mixture. They will also diagnose engine problems. Aerodynamic improvements to reduce drag will also help improve gas mileage. To improve power use of automatic transmissions, a lock-up device (mechanical connection between engine and transmission in top gear) and overdrive will be employed, and there may be an increasing consumer interest in manual transmissions, both as a gas-saving measure and for driving fun. Beginning with 1982 models, passive restraints must be installed in full-size cars. By 1984, all new cars will have them. Padded dashboards, improved bumpers, and other safety features are already familiar to car owners. Economical subcompact pickups, some designed to convert to station wagons, may be offered to compete with Japanese makes while smaller and more economical vans may also be introduced.

CONSPICUITY. HOW TO SURVIVE THE "I DIDN'T SEE HIM" SYNDROME (MOTORCYCLIST VISIBILITY)

A brochure provides safety tips for the motorcyclist to protect him from his greatest single source of danger, i.e. not being seen by other road users. The easiest and most effective way to improve conspicuity is to keep the headlight on during daylight hours. A bright helmet and colorful clothing will attract attention and will provide motorists with a larger visual reference point to gauge motorcycle distance and speed. Fluorescent colors in orange, yellow, and red are recommended. At night, reflective tape on the helmet and reflective trim on clothing are best. At the least light colored clothing should be worn or a reflective vest over dark clothing. All lights on the motorcycle should be clean and operational, and extra reflectors or reflective tape may be used. The motorcyclist should always ride as if he were invisible. He should always ride on the roadway in a lane position where it is easiest for other road users to see him. The left tire track of an automobile is often recommended as the best path in most traffic situations. If following a vehicle, a cyclist should ride where he can see the driver in the vehicle's rear vision mirror. Signals should be used every time a turn or lane change is planned. Flashing the brakelight on and off can be an effective way to indicate an intention to slow down or stop. The horn should be used whenever the motorcyclist has doubts about the intentions of other drivers, pedestrians, or bicyclists.

VEHICLE FUEL ECONOMY REVIEW

From 1974 through 1978, the sales-weighted average fuel economy of new General Motors cars has been steadily increasing. The 1978 fleet average fuel economy is forecast at about 19.0 mpg, or 58% above the 12 mpg figure for 1974. GM expects to meet 1979 and 1980 model year fuel economy standards (19 mpg and 20 mpg, respectively) by extension of its weight-saving program (downsizing), along with emission control and engine improvements, and further use of smaller displacement engines. Between 1980 and 1985 (the standards increasing from 20 mpg to 27.5 mpg), GM cars will have to be redesigned to lose another sizable increment of weight. Substitution of lightweight materials and designs will be utilized to a greater extent. To meet 1980 and 1981 emission control standards, GM has developed the Phase II electronic emission control system. Other areas being pursued in the area of fuel economy are improved engine efficiency, reduced engine size, decreased tire rolling resistance, improved aerodynamics, improved automatic transmissions, and electronic engine controls. GM also has an intensive program directed at application of the diesel engine to passenger cars, to take advantage of its inherently better fuel economy. Progress in electric vehicles includes development of various batteries, notably the zinc-nickel oxide battery, as possible replacements for the conventional lead-acid type.

PASSIVE RESTRAINTS ARE CALLED ANSWER FOR THOSE PEOPLE WHO WON'T BUCKLE UP

The first of two basic types of automatic restraint systems in the U.S. is a safety belt system which is designed to move into place as each front seat occupant enters the vehicle and closes the door. These passive belts, which are available on some cars such as the Deluxe Volkswagen Rabbit and the 1979 General Motors Chevette, require no action on the part of the occupant. Most of these systems have a single diagonal belt (with emergency release) which fits across the chest, plus a padded knee bolster below the dashboard. Some also have an active lap belt. The second type of passive restraint is the air cushion system (ACS), or air bag. This system comprises a sensor in front bumper area (and sometimes a second one on the firewall); a passenger air bag and inflator on the right of the dashboard; a driver air bag/inflator in the steering-wheel hub; and padded or inflatable knee restraints for driver and passenger. Active lap belts will still be required for use with child restraints. An air bag, once inflated in a crash, cannot be reused. Current cost estimates for the air bag system are $100 to $150 above the present cost of safety shoulder belts. The ACS system is expected to be so reliable that the average driver would never experience an inadvertent air bag deployment. In the many years of testing air bags and with 385 known crashes involving air bags, none has failed to inflate. The use of lap belts is recommended with passive restraints to provide additional protection in nonfrontal crashes such as rollovers.

SALE OF USED MOTOR VEHICLES. FINAL STAFF REPORT TO THE FEDERAL TRADE COMMISSION AND PROPOSED TRADE REGULATION RULE (16 CFR PART 455)

A detailed presentation is given of the record establishing the prevalence of unfair or deceptive acts or practices by dealers involved in the sale of used motor vehicles. These practices violate Section 5 of the Federal Trade Commission Act. The following areas are individually discussed: defects; warranties;

prior repairs; prior use; odometers; and make, model, year, vehicle identification number (VIN), and seller. Unfair practices and the legal authority to act against them, alternative remedies and their rationale, the economic effect of the recommended rule (including costs and benefits), and the relationship of the remedy to state and local law are discussed. The rule being recommended would require the posting of a window form on all "used vehicles" sold by "dealers" to "consumers" as those terms are defined in the rule. The window form would disclose, in plain English, information relevant to the purchase decision regarding the condition of the car, the terms of any warranty, the availability of a service contract, prior use(s), mileage, and the name of the person who will settle complaints after sale. In addition, the name and address of the seller and the vehicle make, model, model year, and VIN are disclosed. The rule also has provisions relating to the sales contract, oral statements contrary to rule disclosures, dealer-to-dealer disclosures, record-keeping, foreign language disclosures, and standards for inspecting a vehicle for defects.

VEHICLE NOISE AND THE PASSENGER

Field and laboratory research into occupants' subjective response to in-vehicle noise of passenger cars and heavy goods vehicles (commercial trucks) is reported. The importance of very low frequencies for passenger comfort, as well as the difficulties of accurately reproducing in-vehicle noise in the laboratory are noted. While the principal indicator of the noise in the vehicle is certainly the dB(A) level, the rate of increase of noise with road speed has a bearing on subjective response. The possibility is raised of determining the subjective response to in-vehicle noise by two parameters: the slope of the noise level (dB(A)/Kmh or mph) and the intercept. Considerable evidence exists that currently accepted noise levels in passenger cars and trucks are unacceptable to passenger comfort and probably to optimum driver performance. One reason for lack of improvement is considered to be a lack of criteria for acceptable noise levels. A subjective rating scheme of in-vehicle noise, from quiet (67 dB(A)) to very annoying (91 dB(A)), is tentatively proposed.

BUMPER IMPACTS STUDIED VIA COMPUTER

Computer programs have been developed at Ford Motor Co. to permit evaluation of permanent deflection and denting of automobile bumpers. Using simplified, idealized bumper sections, informed selection from groups of proposed designs is possible at low cost. Test results show good agreement with analytical predictions. Computer programs were run, plotting load and absorbed energy vs. maximum deflection. The best bumper section absorbs the most energy for a given deflection and does not have a widely extended flat portion in its load-deflection curve. Analysis indicates that of three idealized bumpers tested (flat, convex, and concave), those having concave front faces are generally less subject to damage during low speed impact. When actually designing a bumper, factors such as protection for body panels and lamps, styling, package, bumper weight, and surface durability must also be considered.

OCCUPANT-VS-AIRBAG FORCES MEASURED

General Motors researchers conducted static and dynamic tests to investigate the interactive forces between driver surrogates (GM hybrid III anthropomorphic dummy) and the GM air cushion restraint system (ACRS). The driver air cushion module, steering wheel with energy-absorbing column, and associated mounting brackets were used in the test. The crash sensor was not included because the modules were activated remotely. The magnitude of the peak interactive force was found to be an inverse function of the initial separation distance between driver and air cushion in both body block and dummy tests. The peak chest compression occurred when the dummy's chest was against the ACRS module at the initiation of cushion inflation for both static and dynamic test modes and at delayed inflation in the dynamic test mode. Lower magnitudes of chest compression were observed in similar test environments when the cushion was not inflated with the dummy prepostured against the steering wheel or permitted to articulate forward of the upright position. The lowest magnitude of chest compression was observed in a test with the dummy in the upright seated position in which the cushion was inflated before the dummy became significantly involved.

COMPUTER AIDS LIGHTWEIGHT COMPONENT DESIGN (APPLICATION TO AN AUTOMOBILE TAILGATE)

Computer-aided engineering (CAE) was used to evaluate use of alternative materials for optimizing an existing dual-service station wagon tailgate design. The example deals primarily with the design, analysis, and test functions for structures applications, although the general CAE matrix includes other applications in other design phases. Starting with a steel tailgate design, finite element analyses were conducted to study alternative designs maximizing benefits of aluminum, steel, and fiber-reinforced plastic (FRP). Tradeoffs among yield, stiffness, and cost were investigated. Deflections and expense ruled out aluminum configurations, but the initial unit could be redesigned in high strength steel with a 25% weight and possible 10% cost saving. A preferred solution yielded an FRP unit using only two major component parts, saving 35% in weight and costing about 15% more. Weight became the comparison basis, as this was assumed to provide improved fuel economy and more efficient energy use.

DIESEL-STIRLING COMBINATION MAY IMPROVE EFFICIENCY

One diesel specialist expects improved injector designs to couple with silicon-based materials in advancing a small adiabatic diesel engine with reduced emissions. Absence of many cooling-related devices and higher exhaust gas temperatures may make higher thermal efficiencies possible through exhaust-heated Stirling engine applications downstream. An adiabatic diesel's exhaust will be hot enough for the hydrogen-charged Stirling's needs under most operating modes. Since much of the complication, size, and cost of a Stirling engine are in its combustion system, using the diesel's exhaust heat could greatly simplify that engine's design. Use of a heat storage system between the two engines is an interesting possibility. For maintenance of a minimum level in the heat storage, diesel exhaust would be bypassed when it dropped to a preselected minimum. By providing a heat storage of some rational size, surplus energy could be stored and the vehicle operated for limited time periods by the Stirling engine alone. Another approach would be an electric heater in the heat storage, charging it from the power supply, or use of an expander to drive a generator powered by surplus exhaust energy. An air-to-air intercooler will be required for the diesel's combustion air, and liquid cooling for the Stirling's cooler tubes. If recovery of one-third of the diesel's exhaust energy by the Stirling is assumed, a brake thermal efficiency of 60% could be achieved. With such an engine combination, substantial weight reduction in both the powerplant and fuel tank could be realized.

HS-027 508

FATIGUE CRACK INITIATION AND GROWTH ANALYSIS FOR STRUCTURES

The nature of the fatigue process is outlined with fatigue considered as a consequence of cyclic plasticity and local stress and strain as the parameters for fatigue damage analysis. The state of the art of fatigue analysis of structural components is discussed, including the principles of various analytical methods. The similitude requirements are addressed which enable component life predictions to be made on the basis of laboratory data from small specimens. The problem of crack growth prediction is briefly considered. Various studies applying crack nucleation and growth analyses to the prediction of weld life are reviewed. Although significant progress has been made in fatigue analysis, it is realized that the accuracy of predictions is still limited.

SHOT PEENING--AN ADDED DIMENSION

The development of shot peening is outlined as a practical tool to improve the quality of metal parts and structures without increasing size or weight. The process consists of cold working a surface by bombarding it with steel balls and leaving a layer of compressive forces in it. Parameters of the peening operation are discussed: size and velocity of shot, arc height (and Almen strips), coverage, and time. It is noted that the critical factors are built into a modern shot peening machine and are not determined by the operator. Peening applications are discussed. The majority involve increasing the fatigue life of a part, while lesser known ones include the elimination of stress corrosion cracking in aircraft parts. Special mention is made of designing equipment around the benefits of shot peening, as in the case o the single leaf spring used on several modern automobiles. Residual compressive forces imparted by shot peening cancel o minimize the tensile forces caused by service. Additional benefi is obtained by the stress peening process, wherein the part i preloaded as it would be in service, held in that position while peening, and then released. The compressive forces are thereby driven deeper into the surface of the spring.

SOME CONSIDERATIONS IN USING STRAIN-LIFE APPROACH IN FATIGUE DESIGN

The use of the strain-life technique in designing for finite fatigu life is discussed. The technique can be used for both low an high cycle fatigue analysis. The difference in mathematical form of the cyclic stress-strain curve and hysteresis loops is explained

The forms are the same except for a factor of 2 in both stress and strain. Examples are given to illustrate that stronger materials are not necessarily better for fatigue resistance. Stronger materials are better for high cycle fatigue, whereas ductile materials are better for low cycle fatigue. The importance is emphasized of knowing the actual operating conditions of components and structures in designing for finite life. Conditions are derived under which the strain-life and fatigue notch factor-nominal stress range methods yield the same results. A list of materials which satisfy these conditions is included.

HS-027 511

A UNIFIED PREDICTIVE TECHNIQUE FOR THE FATIGUE RESISTANCE OF CAST FERROUS-BASED METALS AND HIGH HARDNESS WROUGHT STEELS

For each of four ferrous-based systems, it is shown that the initiation of fatigue cracks occurs at the tips of microdiscontinuities normal to applied stress under cyclic loading. These disruptions in an otherwise homogeneous steel matrix act as strain and stress concentrators and may be considered from a mechanics viewpoint. The disruptions include graphite flakes in gray cast iron, graphite spherulites in nodular cast iron, gas pores, microshrinkage cavities and inclusions in cast steels, and inclusions in high hardness wrought steels. The four systems exhibit a commonality in that the size and shape of the smallest discontinuity, as well as the strength and ductility of the matrix, govern fatigue resistance. A unified predictive technique for fatigue life is presented which accounts for size effect and plasticity at the tips of the discontinuities (treated as notches). This technique provides an accurate description of the low cycle fatigue resistance and long life fatigue strength of the four ferrous-based systems. Additional research is suggested: extension of the study to nonferrous systems, development of improved (controlled) casting techniques, and application of the predictive technique to other conditions (e.g. cumulative damage analyses).

BEARING LIFE EXPENDITURE DURING RUNNING-IN

Experimental results are presented showing that total bearing wear during running-in (i.e. initial operating period of new machine to reach steady-state friction/wear characteristics), as well as running-in distance, depend on the initial roughness of the journal. Curves based on these results are plotted, which provide a measure of the bearing life expenditure for running-in, and which can be used to obtain optimum values of journal roughness for minimizing this expenditure.

SELECTING EQUIPMENT FOR FAILURE ANALYSIS

Guidelines are provided to aid the field test engineer in determining whether a failed part should be analyzed immediately or returned to the laboratory for analysis. The following six major types of tools used in a failure analysis laboratory are discussed in terms of their most frequent uses: visual, mechanical, optical, chemical, electron, and X-ray. A chart denotes methods of analysis, tools available, and information obtained. Types of equipment are tabulated which are most commonly used for analysis in the four major failure types (yielding, fracture, corrosion, and wear). The availability of resources (time, money, personnel) and the need for proof of accuracy of results are mentioned as factors in equipment purchase. The protection of failed parts during transport to the laboratory is addressed.

POST-PROCESSING GRAPHICS FOR BRITTLE FAILURE ANALYSIS

Using a fracture analysis diagram as the failure criterion, a finite element post-processing scheme is presented as a tool for the analysis of plate structures for brittle failure. The diagram is indexed to the nil-ductility temperature, a material dependent parameter. The dynamic tear test is also used in establishing the diagram. Stress, temperature, and material type information is transferred to the post-processor. Using this information, the processor retrieves the appropriate toughness information from a data file. The stress and temperature data are transformed to an allowable flaw size. The processor prepares the contour of the plate structure on the terminal screen and then maps the allowable flaw sizes as contours onto this outline of the structure. The effectiveness of this approach is illustrated with two examples.

HS-027 516

DIESEL ENGINE DESIGN CONCEPTS FOR THE 1980'S

The differential needle valve nozzle types used on most current diesel engines are discussed in terms of their mechanical limitations. A variable area orifice nozzle is proposed to overcome these shortcomings, resulting in improved fuel atomization and distribution. This design should allow the diesel to realize its full potential of lower emissions, improved combustion, easier starting, and greater air utilization in open chamber, high-speed designs. Some comments are made on air utilization by the diesel engine, noting that engine performance can be improved through close attention to the effect of nominal compression ratio on trapped cylinder volume, surface/volume ratio, and ratio loss. Two adiabatic diesel engine design concepts that have the potential for much lower specific fuel consumption are discussed: turbocharged two-cycle diesel and diesel-Stirling thermal engine combination. It is concluded that the successful development of a small adiabatic design, open chamber, direct injection diesel utilizing exhaust energy recovery, equipped with the proposed nozzle design could provide more than 50 mpg on diesel fuel powering a 4500 lb car, giving adequate performance with 185 hp and lower emissions.

DIESEL ENGINE MANUFACTURING IN THE 1980'S

A successful diesel engine manufacturing operation in the 1980's requires a close working relationship between product and manufacturing groups, and a total system integration of manufacturing facilities. To design and develop engines which meet product demand and which include appropriate advanced technologies require a strong positive relationship between product and manufacturing engineers. This cooperative effort starts with the initial concept and continues through prototype development, resulting in a more cost-effective product and reduced development times and costs. Manufacturing engineers are responsible for system integration which involves organizing new manufacturing elements on a system basis, evaluating and modifying existing systems for optimum effectiveness and linking new and existing systems for factory-wide integration. The major areas of system integration are asset utilization, group technology, ma
facturing systems, simulation, preventive maintenance, and
ployee training.

AUTOMOTIVE FUELS FOR THE 1980'S

Data are reviewed on the past, present, and projected futu
energy situation: energy consumption by end use and by sour
in the U.S., oil consumption by end use and by transport mo
in the U.S., and world oil supply. The end products from
barrel of crude oil, and proven and recoverable world crude
reserves are considered. In particular, 71% of all energy used
U.S. transportation is consumed by gasoline engines, represen
ing 20% of total energy consumption. Motor gasoline accoun
for the largest share of the crude oil barrel, or 39%. In the lo
run, energy-efficient vehicles must be designed with engin
tolerant of a wider range of fuel characteristics. Since futu
transportation fuels will be produced from sources other th
crude oil, their compatibility with future engines must be a
sured. In this light, current fuel requirements for spark igniti
engines are discussed in terms of volatility and octane requir
ment. Options available to the engine designer to impro
engine fuel tolerance are reviewed (e.g. combustion chamb
configuration, electronic ignition timing). The Ford Pr
grammed Combustion Process Combustion Chamber design

cited as an example of a fuel-efficient, high compression ratio engine with a modest octane requirement. It is a direct cylinder injection, stratified charge engine. Diesel fuel requirements (low contamination, apprpriate cetane rating, cloud point, sulfur content, flow properties) are discussed and exhaust emission standards are mentioned as the determinant of the diesel engine's future. Of internal combustion engines suitable for surface transportation, the gas turbine is cited as tolerating the broadest range of fuels, although fuel economy improvement awaits new turbine materials technology.

DRIVER EDUCATION EVALUATION TESTS. SUMMARY REPORT

Four tests were constructed to evaluate driver education students or programs in achieving or providing driving knowledge, driving performance, good driving attitudes, and driving aptitudes. For knowledge, performance, and aptitude tests, validity was measured by the ability of each test to discriminate student drivers from professional fleet drivers. For the attitude test, validity was measured by the ability of the test to discriminate students from ordinary experienced drivers and from experienced drivers with accident records. The tests cover a range of driving-related skills and knowledge; all four tests exceed standards of acceptable validity and reliability as defined by testing literature and industrial usage. The tests are useful as intermediate instruments for evaluating driver education (individual students or groups of students from different programs). A detailed description of each test encompasses test administration and practical limitations, validity analysis and establishment, and relilability analysis and establishment. Supporting data and references are provided. A driver information sheet is appended.

CHILDREN IN MOTOR VEHICLES. NEVER TOO YOUNG TO DIE

A study of 89 motor vehicle occupant deaths in Maryland among children less than 15 years of age compared these fatalities in terms of factors generally associated with greater risk of injury or death. Exposure factors were considered by comparing children killed in crashes with all children in Maryland crashes reported to the police. Data extracted from postmortem records (1973-1977) and state police accident reports concerned age, restraint use, seating position, injury description, and crash circumstances. Similar data for 1977 were determined from tabulations of the Maryland Automated Accident Reporting System. Of 89 children killed, 38 or 43% were less than 5 years old. The occupant death rate, estimated from 1973-1977 deaths and 1977 crash data, was 6.4 per 1000 ocupants for children less than 1 year old and 1.0 per 1000 for other children. Most children traveled completely unrestrained; 55% rode in the vehicle's front seat; and all deaths resulted from impact injuries except for three children who died in fires caused by the crash. Serious head injuries were sustained by at least 66 children and were most common in children less than 2 years of age. Fifty-four children died at the crash scene or were dead on arrival at the hospital. Crashes between noon and 6 P.M. dominated for children under 1 year. Among older children, crashes between 6 P.M. Friday and Sunday midnight predominated. Ejection from the vehicle was least common in children under 1 year. Ninety percent of all children less than 10 years old and 50% of older children were killed in multiple vehicle crashes. Study results are consistent with national data showing that occupant death rates for preteenage years are highest in the first year of life and that the median age at death during this year is four months. The findings indicate the potential value of head protection for young children, and the greater value of restraint systems for all occupants. Restraint use by young children was estimated as 25% of adult use in the same vehicle. The need for automatic crash protection is emphasized.

ACCIDENT RESEARCH MANUAL. FINAL REPORT

Techniques are compiled for use by engineers/analysis in carrying out highway accident research. Many highway safety research studies are inadequate due to erroneous conclusions or lack of conclusive evidence. The accident research manual contains materials on: rationale of and need for improving the level of existing research; issues with which researchers must be familiar; components and methodologies used in basic accident research types (research to evaluate countermeasures and to identify and examine relationships between accidents and other highway factors); preparation and distribution of research results; and guidelines for engineer/analysts to use in research. The manual is designed for use in classroom training, as a reference text, and/or in self-study programs. Review questions, self-study tests, and references to relevant texts and articles are included.

SEAT-BELTS. A STUDY OF THEIR EFFECT ON 3,000 ACCIDENTS

Statistics from a study of 3,138 cars involved in accidents are presented. In a sample of 1,624 persons wearing seat belts, 3% were killed in accidents, 7% were heavily injured, 55% were slightly injured, and 35% were uninjured; of the 3,242 individuals without seat belts, 7% were killed, 12% were heavily injured, 63% were slightly injured, and 18% were uninjured. Seat belts provide two kinds of protection: preventing ejection from the vehicle; and keeping the person from hitting against interior car parts (secondary collision). In head-on collisions, 6.2 of every 1,000 people riding in the front seat without a seat belt are killed by ejection. Passengers are better protected by seat belts than drivers since drivers tend to hit the steering wheel and steering mechanism. Of all body parts, the head is most protected by seat belts. Supporting data and illustrations are provided.

PUBLIC AND PRIVATE COORDINATION NEEDED IF AUTO REPAIR PROBLEMS ARE TO BE REDUCED. REPORT TO THE SENATE COMMITTEE ON COMMERCE, SCIENCE AND TRANSPORTATION AND ITS CONSUMER SUBCOMMITTEE

Ways in which Congress could strengthen the Federal role in reducing consumer auto repair problems were explored in an investigation by the General Accounting Office (GAO), involving consultation with officials and review of programs of 11 Federal agencies, seven states, four U.S. auto manufacturers, and several other industry and consumer groups. Questionnaire returns were also received from over 250 government and industry officials. Auto repair was identified as a major consumer problem. Consumers were bothered by faulty and unnecessary repairs, and unanticipated repair costs. Government officials viewed auto repair problems as serious, expensive, and persistent although industrial officials believed that these problems were exaggerated. It was determined that problems are partially caused by a shortage of skilled mechanics and by questionable business practices. It was also determined that state and industry efforts to minimize auto repair problems must be evaluated. Consumer information and education programs are recommended, as well as dispute resolution programs. Mechanic competency and industry repair practices must receive increased attention. State and local officials feel that their regulatory authority may be too limited. Federal involvement in the auto repair problem is mostly indirect, and Federal activities have had minimal effect. State and local government officials see a need for some Federal involvement. An interagency coordinating committee is a step toward a national program dealing with auto repair problems.

MOTORCYCLE ACCIDENT INVESTIGATION 1975, 1976, 1977, 1978. A FOUR YEAR ANALYSIS OF MOTORCYCLE SAFETY IN UTAH

Circumstances influencing motorcycle safety in Utah from 1975 through 1978 are analyzed. A seven-phase countermeasure program was initiated to deal with motorcycle crashes. After evaluation, four countermeasures were retained: enforcement, pub
information, legislation, and problem identification. The othe
driver education, driver licensing, and judicial, were either d
continued or merged into other general problem areas. T
issue of major concern to the state is the value of protecti
headgear in motorcycle crashes. The value of safety helmets
specifically equated with their role in preventing head injuri
helmets do not curtail motorcycle crashes. In the analysis
1975-1978 motorcycle fatalities, a majority of drivers not we
ing helmets died of head injuries; of drivers who wore helme
fewer died from this cause. Rates of helmet use decreased fr
about 78% in 1975-1976 to about 34% in 1977-1978 as a res
of amendments to Utah's helmet use law during 1977. Effects
decreased helmet use may be reflected in the increased he
injuries in 1977-1978 data. The most significant factor related
motorcycle crashes is speed, followed by reckless driving
drinking. Motorcycle size and motorcycle driving experie
are also important.

STIRLING ENGINES FOR AUTOMOBILES

The ability of the Stirling engine to meet low-cost mass prod
tion, high efficiency, low emission, extensive low part po
operation, and fast response requirements is assessed. Since
Stirling engine is relatively undeveloped with no base of
duction engine experience for any application, the Ford Mo
Co., funded by the Department of Energy, initiated work
1977 to establish the fuel economy potential of the Stirl
engine in the automobile. As of September 1978, Ford proj
a fuel economy improvement of 38-81% beyond that of
baseline spark ignition engine of the same class and perfo
ance. The two most significant improvements relate to en
reoptimization, including improved efficiency in the low-po
operating region, and to power control system modification
appears that a 50-60% improvement in metro-highway
economy is a reasonable goal for the automobile Stirling eng
Key technology needs include low-cost high-temperature m
alloys for heater heads and long-life low-leakage shaft s
Current Stirling engine development efforts are being condu
by a team consisting of Mechanical Technology Inc., Un
Stirling of Sweden, and AM General.

THE EFFECTIVENESS OF ACCREDITED TRAFF VIOLATOR SCHOOLS IN REDUCING ACCIDEN AND VIOLATIONS

The California State Legislature enacted Senate Bill 193 in
requiring the Dept. of Motor Vehicles to establish an accre
tion program for traffic violator (TVS) and driving under
influence schools. The TVS accreditation program was eva
ed using 14,278 convicted violators selected (Aug-Nov

from cooperating courts that assigned violators to traffic schools. Schools were required to complete a coding form for each subject, giving the driver's license number, birth date, school start date, court identification code, and school identification code. Biographical data, three-year prior accidents and countable convictions, subsequent six-month accidents, and six-month total convictions plus failures to appear were obtained from the Dept. of Motor Vehicles' central computer records. Accidents included the total number of fatal/injury and property damage accidents reported by the California Highway Patrol, property damage accidents reported by involved drivers pursuant to California's financial responsibility reporting law, and all known out-of-state accidents. Violators convicted of a nonalcohol-related traffic offense were randomly assigned to groups attending or not attending a TVS. Although some subjects were assigned to the wrong treatment group, both groups were similar in their composition based on sex, age, and prior driving record. To guard against misinterpretation, subsequent accident and conviction data were further analyzed by placing all subjects in the group to which they should have been assigned and by using only schools which had properly assigned subjects. Both analyses confirmed that treatment did not have a significant effect on subsequent six-month accidents or convictions. No evidence was found that treatment had different effects within school types (public versus private or multiple versus single session). Study findings question the efficacy of TVS's. Information on TVS accreditation standards and supplementary study data are appended.

WHO NEEDS AIR BAGS?

Issues are addressed related to the efficacy and acceptance of air bags in automobiles. Three facts underlie the controversy over air bags: solid data are lacking to support the assumption that air bags will automatically guarantee a high degree of safety to people riding in front seats; air bags are designed to function in head-on or near-frontal crashes, offering little or no protection in side, rear, roll-over, ricocheting, and low-speed accidents; and shoulder harnesses (with lap belts) provide more protection in the full spectrum of accidents than air bags alone and are about the equivalent of air bags and lap belts combined. The National Hwy. Traffic Safety Administration advocates the use of air bags since only one in seven persons uses seat belts. The initial and replacement cost of air bags is much higher than that of seat belts. Passive (automatic) belts require two separate front seats and can be dismantled. Air bag operation is illustrated and explained, studies on the lifesaving potential of air bags are questioned, and cost implications of air bag use are discussed.

KILLERS ON THE ROAD

The traffic accident situation in the Philippines is outlined and efforts to reduce such accidents are considered. According to the Constabulary Hwy. Patrol Group, one of the country's traffic law enforcement agencies, 34,612 traffic accidents occurred in 1977 compared with 18,510 in 1976. Nearly 1,000 persons died from traffic accidents in 1977, and more than 11,500 persons were injured. It is estimated that 94 traffic accidents occur daily, or at least one every 15 minutes. An average of three persons die in these accidents, and another three are injured every two hours. Most accidents occur during rush hours from 10 a.m. to 1 p.m. and from 6 p.m. to 8 p.m. The most accident-prone days of the week are Saturday, Sunday and Wednesday. Most accidents involve collisions between two more vehicles. Drunkenness, sleepiness, and physical defects are major accident causes. Another factor is that the number of roads built annually is not commensurate with the number of cars manufactured daily. Some traffic-related agencies blame accidents on lack of traffic signs and traffic control devices to regulate vehicle and pedestrian flow. Compounding the traffic problem is a lack of medical facilities and physicians to treat victims. One physician has proposed the creation of special units in Philippine provincial and regional hospitals to deal exclusively with accident cases. Efforts are being intensified by various organizations and agencies to prevent traffic accidents, including seminars on better driving, research, and the use of junior traffic aides to supervise pedestrian crossings near schools. Laws have been passed to promote accident prevention, but no laws mandate the use of safety belts in cars.

CRASH PROTECTION IN ROAD ACCIDENTS

Active and passive crash protection in road accidents is examined, with reference to highway safety in developing countries. In general, road accidents consume roughly 1% of the gross national product of most countries, whether industrialized or developing. Due to the relatively great effectiveness of crash protection measures and restraint systems, benefits of their use are likely to outweigh costs. Most road vehicles are passenger cars and the majority of road injuries are to car occupants or pedestrians. In global terms, about 40% of fatalities involve car occupants, 30% involve pedestrians, and 20% involve motorcyclists. Advances have been made in developing countries in the adoption of protective devices and restraint systems. The most significant active crash protection device is the seat belt. Other effective active measures are crash helmets for motorcyclists, and child restraint systems and head restraints for car occupants. Most passive devices are incorporated into the vehicle's basic design, e.g., energy-absorbing instrument panels, anti-intrusion steering assemblies, high penetration-resistant laminated wind screens, antiburst door locks, and improved seat design. The risk of accidents with casualties is considerably higher for mopeds and motorcycles than it is for cars. The importance of public health measures and road safety programs in developing countries is emphasized.

TRANSIT FACT BOOK. 1978-1979 ED.

The 1978 annual summary of trends in U. S. urban mass transportation is presented. Growth in public transportation is projected for the 1980's, particularly in consumer demands for improved services caused by the rapidly changing transportation environment, higher gasoline prices, and public education programs on transit system use. Data on the U.S. transit industry concern the number of operating transit systems, passenger vehicles owned and leased, total operating revenues, linked and unlinked transit passenger trips, estimated passenger and vehicle miles, and energy consumed. Passenger vehicles are classified as heavy and light rail cars, trolley coaches, cable cars, inclined plane cars, aerial tramway cars, motor buses, Automated Guideway Trasit cars, commuter railroad cars, and urban ferry boats. Energy data encompass diesel fuel, gasoline, propane, and electricity. Transit industry trends and issues are explored, and a profile of transit services is provided. A glossary and an index are included.

ENERGY CONSERVATION POTENTIAL OF OFF-HIGHWAY RECREATIONAL MOTOR VEHICLE. REPORT TO THE CONGRESS

General characteristics of off-highway recreational motor vehicles are defined, including industry, market, and owner characteristics; possible fuel conservation options under alternative scenarios; estimated fuel conservation potential; and general recommendations for future fuel conservation programs. The focus is on land-based recreational motor vehicles, recreational motorboats, and general aviation aircraft (single-engine and twin-engine piston). Since conservation efforts directed specifically toward the recreational vehicle sector may not yield a net decline in total energy or even gasoline consumption, it is difficult to establish what leisure time activities are most wasteful of energy. Total land-based recreational motor vehicle gasoline consumption in 1977 was about 1.6% of passenger car consumption and 1.2% of consumption by the entire transportation sector. Improvements in technology and operating-maintenance procedures can reduce fuel consumption. Absolute fuel savings are small compared with projected passenger car fuel savings. Certain market forces, e.g. fuel availability, fuel prices, and general inflation, tend to dampen the acquisition and use of recreational vehicles. Relatively little is known about leisure time tradeoffs with respect to fuel conservation. It is recommended that Federal programs concentrate on educational and promotional activities designed to increase fuel efficiency through improved operating-maintenance procedures; that Federal programs avoid implementing programs which reduce recreational vehicle inventories or use; and that cost be considered in implementing any Federal programs specifically directed toward the recreational vehicle sector. More reliable and definitive industry and consumer data on fuel economy of land-based recreational motor vehicles should be obtained. Fuel conservation options and mechanisms are described, and fuel conservation potential by 1985 is summarized.

LONG LIFE RANDOM FATIGUE BEHAVIOR OF NOTCHED SPECIMENS IN SERVICE, IN SERVICE DUPLICATION TESTS, AND IN PROGRAM TESTS

The actual service fatigue life of notched steel and aluminum specimens was determined using a special testing device installed in a passenger car and operated by a car rear wheel's vertical displacement; specimens were subjected to reversed bending. Service, service duplication, and program fatigue tests were conducted. Random fatigue life curves obtained by service (road) tests, expressing the relation between maximum incremental stress and the number of mean crossings to failure, did not differ significantly form those obtained by service duplication (laboratory) tests when considering scatter in fatigue. There was a tendency toward shorter fatigue life from service tests as opposed to service duplication tests, which may be explained by corrosion in service tests. While road testing took several years to complete under changing environmental conditions, laboratory testing could be carried out without interruption and under constant test conditions. Program fatigue tests, the most frequently used type of simulation for field loading histories, overestimated fatigue life. Results confirmed that valid fatigue life prediction models must account for the sequence of individual peaks and troughs.

THE EFFECT OF HEARING PROTECTORS ON THE PERCEPTION OF WARNING AND INDICATOR SOUNDS--A GENERAL REVIEW

Available literature is reviewed on auditory effects of wearin hearing protectors. A conceptual model of the perception o auditory signals suggests that three components are importan (audibility, attention demand, and recognition). Several method are compared for predicting the audibility of complex sounds i noise. Limited experimental evidence on auditory effects o wearing hearing protectors is examined within the framework o the perception process conceptual model. The use of hearin protection by people with normal hearing will not have an marked effect on the audibility of sounds in high-level continuous background noise. In intermittent or time-varying noise, th use of hearing protectors may cause a relative disadvantage t the wearer during quieter periods. Inconsistent use of hearin protectors may result in signals being inaudible when subs quently wearing protectors, via a temporary shift in the hearin threshold. It is hypothesized that by damping and changing th spectral character of sounds, hearing protectors may impa their attention demand value and recognition. An evaluation workers who suffer from noise-induced hearing loss indicat that their perceptions of sounds in noise may be governed wh wearing protectors by doubly elevated absolute threshol rather than by masked threshold criteria relevant to colleagu with normal hearing. Response to warning sounds is discusse An informal survey of acoustic warning device manufacture suppliers, and users is appended.

DIAGNOSTICS OF GEAR ASSEMBLY--A NEW APPROACH USING IMPACT ANALYSIS

A technique employing torsional excitation and an accelerometer fitted to the structure is used to estimate the backlash distribution of gears in mesh. Backlash may arise from misalignment, eccentricity, or casing distortion. Most mechanical systems containing backlash or clearance can be investigated using a simple nonlinear model. In the impact method, by applying constant force excitation to the mass while crossing the clearance, actual impact velocity at contact will be a function of clearance. Thus, to a first order, impact velocity can be estimated by analyzing structural impact acceleration. Application of the proposed technique involving torsional excitation and an accelerometer will result in detailed phase and amplitude information about geometric imperfections in the gear assembly. Phase lags of particular noncircularities can be related to gears in an absolute sense, but amplitude information can only be treated as normalized to the gear itself. Results can then be compared within the gearbox or perhaps for a number of gearboxes. Results can be applied to match circular imperfections of gears to eccentricities of their shaft-bearing mounts in certain cases. Repeated tests for detecting wear throughout the gear system represent another possible application.

PERCEPTUAL/COGNITIVE SKILLS AND DRIVING: EFFECTS OF BRAIN DAMAGE

The relationship between perceptual/cognitive skills and driving was investigated by studying 23 persons with brain damage, 8 persons with spinal cord damage, and 10 able-bodied controls. Each subject was evaluated using a battery of perceptual/cognitive tests, a set of driving tests in a parking lot, and actual intraffic driving. Driving performance was significantly correlated with perceptual/cognitive skills. Highest correlations were obtained for a picture completion test, a picture arrangement test, and a motor free visual perception test. Persons with brain damage performed significantly worse than control subjects and people with spinal cord damage on a range of perceptual/cognitive tasks. Persons with brain damage exhibited impaired driving performance compared to that of control subjects and people with spinal cord damage. There was high correlation between subjective evaluation of driving potential by a driver trainer and evaluation of selected driving actions. Findings suggest that perceptual/cognitive tests can be used in screening to detect potentially serious driving-related problems. Data support the hypothesis that brain damage affects perceptual/cognitive skills and, consequently, driving performance. Study forms are appended.

A REVIEW OF NHTSA'S (NATIONAL HWY. TRAFFIC SAFFETY ADMINISTRATION) VEHICLE COMPLIANCE TESTING POLICIES AND PROCEDURES

Policy issues are addressed related to compliance testing of vehicle and equipment by the National Hwy. Traffic Safety Administration under Federal Motor Vehicle Safety Standards. Five major topics are explored: extent to which OVSC (Office of Vehicle Safety Compliance) testing policies and procedures enhance prospects for successful litigation; role of the Vehicle Selection Matrix in constructing the test program; the OVSC budget development process; impact of changes in resources spent on vehicle and equipemt testing; and use of acceptance sampling plans as an alternative to current sampling practices. The compliance testing process is briefly described. Acceptance sampling and other statistical approaches to compliance testing are detailed.

SEAT BELT AORTA: ACUTE DISSECTION AND THROMBOSIS OF THE ABDOMINAL AORTA

A clinical case is reported involving a 65-year old woman who suffered an acute dissection and thrombosis of the abdominal aorta as the result of a lap-type belt injury in an automobile accident. The injury resulted in the first reported case of complete occlusion of the abdominal aorta as the patient died of a myocardial infarction 3-1/2 hours after surgery. Two previously reported cases are reviewed in which lap belt injury resulted in a later diagnosis of partial vascular occlusion. The effect of deceleration forces in an automobile accident upon the circulatory system is hypothesized. As the occupant's body rotates about the axis of the seat belt, the resulting longitudinal deceleration force drives the blood in the dorsal aorta in the cranial direction toward the aortic arch, causing a sudden stretching force upon the abdominal aorta, which is compressed against the spine by the thrust of the seat belt on the abdominal contents. Upon impact and spinal flexion, the abdominal contents are forced into the pelvic cavity and the aortic arch is stretched in the caudal direction. Transverse ruptures, as are reported here, indicate longitudinal tension on the aortic tube. Another mechanism which may be involved in aortic dissection is the immense force of shock waves moving along the aorta. The findings indicate that thorough examination of the abdominal aorta is mandatory at laparotomy, and that patients with lap belt injuries should be followed up after discharge from the hospital.

PLASTIC GETS TOUGH

Lightweight composite plastics are challenging steel and aluminum in applications ranging from house walls to aircraft wings. One of the major composite discoveries is graphite fiber. Although carbon (or graphite) fiber is expensive, fortunately it can be easily united with common fiberglass, epoxy, or polyester resins, resulting in a product that has the best features of both materials. Among many applications, graphite supercomposites are being used to make lightweight airplane wings (for Marine Corps AV-8B VTOL and Navy Hornet aircraft), filters on communications satellites, and golf clubs. General Electric's new composite, Valox, is being used in the upper housing and handle of hand irons. Du Pont's Zytel ST (Super Tough), a nylon resin, is being stamped into one-piece, five-spoke bicycle wheels. Celanese uses an advanced polymer called Celcon for faucets and bathroom fixtures. Two new composites show particular promise for home construction: Tapecrete (developed by two Canadian engineers), a cement combined with a polymer and reinforced with fiberglass fabric; and Envirez, a fire-resistant, lightweight, fiberglass-reinforced product (PPG Industries). To reduce automobile weight for improved fuel economy, automakers are using more composites and aluminum, as well as high strength steel. Composites, confined until recently to noncritical parts, are now beginning to appear as structural components (e.g. body panels, bumper beams). Celanese and PPG have combined graphite and fiberglass with new resin and new winding techniques to make an automotive driveshaft with twice the strength of steel.

WILL THERE EVER BE HAPPINESS IN TIRE LAND?

The combination of high interest rates, high gasoline prices, and a debt-laden public resulted in lower sales of new cars and trucks and replacement tires of all types in the U.S. during 1979. Total passenger car replacement tire shipments from manufacturers to dealers were 12 million units below expected figures in 1979. The domestic manufacturers' plight was further exacerbated by continued growth in the market share of imported or domestically produced Michelin tires. By the second half of 1979, domestic tire manufacturers operated their plants at only 80% of available capacity, compared to well over 90% in the first half of the year. There were numerous plant closings, with more to come to bring supply into balance with anticipated demand. A 4.4% decline in total tire shipments is projected for 1980, with the passenger replacement market dropping 1.8%. Production is expected to fall by 6%. Independent tire dealers will take an increasing share of the total tire and automotive maintenance business in the 1980's. These dealers, as well as the tire manufacturers, will need to consolidate. The tire dealer is advised also to narrow his product line to reduce inventory costs.

CALCULATION OF FUEL CONSUMPTION DUE TO TRAFFIC CONGESTION IN A CASE-STUDY METROPOLITAN AREA

For the Milwaukee, Wis. metropolitan area, an analysis wa
made of potential fuel consumption reductions brought about b
reduced delays through traffic engineering techniques or othe
changes that expedite traffic flow, and by reduced congestion c
peak-period traffic through flexible or staggered work hour
An equilibrium traffic assignment algorithm was used to dete
mine speeds and flows on the road network, and a travel-time
fuel-consumption relationship was used to translate the reduc
tions in travel time into reductions in fuel consumption. Actua
travel time and flow data were used to check the results c
traffic assignments. Upper bound figures for reduced fuel con
sumption were estimated to be 4.1% for elimination of conge
tion-related delays and 2.8% for reduction in peak traffic vo
umes. Actual reductions in fuel consumption realized by thes
two approaches would be smaller than these estimates.

INSURANCE FACTS. 1979 ED.

Basic facts and dimensions are presented on the property and liability insurance business in the U.S., including a review of 1978 business. Dollar value of premiums written for the various types of insurance are tabulated for each year from 1954 through 1978. Total of premiums written in 1978 for all types of insurance was approximately $162 billion; purchases increased almost 13%. Automobile insurance is the largest single classification of the property-liability business. The premium volume of approximately $33.2 billion in 1978 was about 9.5% higher than 1977 and more than double that of 1971. Historical data on losses resulting from fires, natural disasters, accidents, and crime are tabulated and discussed. For motor vehicle accidents, data are presented on fatalities and injuries, driver age, repair costs, economic losses, and claim costs. A study by the Insurance Inst. for Hwy. Safety which found that the latest Federal bumper standard had little effect on the vulnerability of 1979 models to costly damage in low-speed impact tests is reported. Background information is presented on determination of insurance rates, automobile financial responsibility laws, no-fault automobile insurance, and insurance regulation (state regulatory authorities listed). National organizations representing or supported by insurance companies are listed, including various state organizations subscribing to Insurance Information Inst. services.

EFFECT OF WHEEL SUSPENSION TYPES ON WHEEL LOAD AND SIDE FORCES (EINFLUSS DER RADAUFHANGUNG AUF RADLASTEN UND SEITENKRAFTE)

Equations of motion were derived for a rigid axle and an independent wheel suspension, using a fixed vehicle body. The four different road surface irregularity inputs (roughness functions) were two vertical excitations on the left and right sides and associated angular excitations. For excitation of the rigid axle, four other roughness functions were defined: stroke, roll, and in-phase and out-of-phase camber excitations. Required spectral calculations were obtained. Wheel load fluctuations, side forces on the rim, and the total horizontal forces acting on the two wheels of one axle were calculated as a measure of lateral adhesion efficiency on a straight roadway. The benefits of independent wheel suspension systems were demonstrated.

APPROACH TO ASSESSING THE IMPACT OF ENERGY CONSERVATION POLICIES ON TRANSPORTATION DEMAND

Seven classes of energy conservation policies are examined: to increase automobile travel cost relative to other travel modes; to limit automobile fuel supply available to travelers; to physically limit automobile use; to change automobile characteristics; to change characteristics of nonautomobile transportation systems; to affect geographic distribution of trip ends; and to attempt to directly change travel patterns. The impact of these policies on trip makers' decisions is assessed in terms of: reduction in travel, change of trip purposes, mode shift, use of more efficient cars, relocation, and peak-hour use shift. The ability of the models traditionally used for forecasting transportation demand to assess the impacts of these policies is examined. Where available modeling devices appear unable to deal with policy effect on overall travel demand and modal choice, preliminary suggestions are made for revisions to the models. Modal shift (i.e. from private to public transportation) is one of the most probable and highly important trip maker responses. More work is required to improve the sensitivity of these mode-choice models to energy conservation policies and to integrate the improved models into the total transportation demand-forecasting process.

SURVEY AND ANALYSIS OF ENERGY INTENSITY ESTIMATES FOR URBAN TRANSPORTATION MODES

Some of the standard methodologies and data sources employed to estimate the energy intensiveness of urban transit modes are reviewed, with emphasis on aggregate statistical measures. A very small repertory of methodologies/sources underlie energy intensity (EI) estimates, and variance among their results is primarily attributable to contradictory load-factor assumptions. EI estimates for bus and rail transit are developed, and the inadequacies of automobile data are discussed. The best evidence available indicates that buses are substantially more energy efficient than heavy rail transit and that existing rail transit systems consume an average of 24% more operating energy per passenger/km than do buses. Modern heavy rail systems consume approximately 100% more energy/passenger km than do buses, not even taking into account the huge construction costs. Light rail systems, on limited evidence, seem to have no advantage over heavy rail in operating energy efficiency, but may offer some savings in construction costs.

FOREIGN OIL DEPENDENCE: STATE-LEVEL ANALYSIS (NEW YORK)

The dependence of New York State on foreign sources of petroleum products is discussed, including direct product imports and imported crude oil that is domestically refined into such products. By use of a generalized allocation procedure that is applicable to all states, the original foreign sources of petroleum products are traced back from major East Coast and Gulf Coast refineries to the particular countries that supplied the imported crude oil. Known imports of refined products are then added to these estimates to obtain estimates of total dependence. Four products are studied: residual oil, distillate, gasoline, and jet fuel. Results show that, overall in 1976, New York is 72% dependent on foreign oil, compared with 43% for the United States. For residual oil, New York is 96% foreign dependent; major suppliers are Caribbean and South American countries, particularly Venezuela, Virgin Islands, and the Netherlands Antilles. For distillate, gasoline, and jet fuel, New York is between 54% and 58% dependent on foreign sources; supplies come mainly from African and Middle Eastern countries, particularly Nigeria, Algeria, and Saudi Arabia. The United States' dependence pattern is similar but less severe and broader in base. Although New York, like many states, gets its oil from many countries, it relies primarily on a relatively small number of suppliers for most of its petroleum products, making it particularly vulnerable to supply curtailments. A number of actions are suggested to broaden New York's base of sources, to cut foreign dependence, and to reduce petroleum use. These include conservation, fuel substitution in industrial and domestic applications, conversion of existing heating systems to non-oil fuels, and improved fuel use in the transportation sector.

VEHICLE KILOMETERS TRAVELED: EVALUATION OF EXISTING DATA SOURCES

Existing data sources for vehicle kilometers traveled (VKM
and gasoline consumption are evaluated. Collection, reporti
consolidation, and estimation procedures are addressed. Si
direct measurement of VKMT has never been made, the ava
ble information consists of indirect estimates based on vari
sets of assumptions. The type of assumptions and the reliabi
of the data determine the models and types of hypotheses t
can be meaningfully tested. Historically, the importance
VKMT accumulation has been directed toward highway pl
ning and has included such areas as traffic density, highv
safety, and other non-energy-related areas. For those efforts,
traffic-counting methodology has been the procedure m
widely used by the individual states to estimate VKMT. Si
the 1973 energy crisis, the Federal Hwy. Administrat
(FHWA) has requested that the states base their estimates
VKMT on average fuel efficiency rated for different veh
classifications. This alternative methodology may be a m
appropriate way to solve energy-related issues, because ene
efficiency is one of the predetermined variables. Fuel consu
tion rates, however, involve many heterogeneous inputs, an
has been difficult to arrive at a meaningful state average for
economy. As the FHWA has not established a specific meth
ology for estimating VKMT or a single procedure for coll
ing, reporting, and consolidating VKMT data, an accurate
reliable estimate of VKMT in the U.S. cannot be obtai

MULTIVARIATE CLASSIFICATION OF AUTOMOBILES BY USE OF AN AUTOMOBILE CHARACTERISTICS DATA BASE

A cluster analysis of 125 models of 1975 automobiles was
ducted in order to aggregate the vehicles into homoger
groups suitable for modeling automobile demand by ve
type. Eight variables extracted from an automobile charac
tics data base developed by the Dept. of Transportation
employed: curb weight, wheelbase, engine displacement, ro
ness, passenger capacity, fuel economy, list price, and powe
weight ratio. Several weighting schemes, two-distance me
and hierarchical as well as nonhierarchical clustering techn
were used. The analysis strongly indicated that two- anc
group configurations were important. Within the six-group
tering, the three groups that had the highest average sea

liter and seats/initial cost comprised more than 80% of 1975 sales. Compared with the Wharton five-group classification used in a recent econometric automobile-demand model, the multivariate clustering did a consistently better job of accounting for the variability of vehicle characteristics.

POLICY CONFLICT--ENERGY, ENVIRONMENTAL, AND MATERIALS: AUTOMOTIVE FUEL-ECONOMY STANDARDS' IMPLICATIONS FOR MATERIALS. REPORT TO THE CONGRESS OF THE UNITED STATES

The possible effects on the supplies and prices of four basic industrial materials (iron and steel, aluminum, plastics, and rhodium) were never explicitly evaluated by the Federal government before the automobile fuel economy standards were adopted. The standards, enacted to reduce expensive oil imports, may result in increased aluminum imports of greater dollar value than can be saved by reducing oil imports. Thus U.S. balance-of-trade deficit may suffer rather than benefit. To meet fuel economy and air quality standards at the same time, automobile pollution control devices may require more rhodium than will be available and may force the price of this scarce metal drastically higher. Neither of these consequences, which contribute to unstable, inflationary materials markets, was foreseen when the standards were enacted because the government made no systematic appraisal of their impact on materials. On the whole, the complex and competitive relationship among national goals for energy, the environment, and materials has not been recognized in Federal policy formulation. Therefore, a method for resolving policy conflicts is needed, which may be brought to light through coordinated economic and policy analysis.

ACCIDENTS AND THE NIGHTTIME CONSPICUITY OF TRUCKS. FINAL REPORT

Three independent but related studies are compiled on truck conspicuity and truck-car collisions. The first paper, a review of Fatal Accident Reporting System (FARS) data, indicates that most fatal car-into-truck accidents occur during hours of darkness, pointing to a potential lack of nighttime truck conspicuity. The second paper, a review of the literature on conspicuity and retroreflectorization, suggests that retroreflectorization of trucks is likely to increase their nighttime conspicuity. The third paper details an exploratory field study which indicates that conspicuity-enhancing retroreflective treatments applied to the rear and sides of trucks caused drivers to look at trucks more often and at greater distances.

AN APPRAISAL OF AGGREGATE AND DISAGGREGATE CAR OWNERSHIP FORECASTING METHODS

Results are presented which support the proposition that the growth path for cars per person should be sigmoid with a finite saturation level. The fact that projections of car ownership using the logistic curve have consistently tended to be too high suggests that a sigmoid curve convex, rather than linear, in the "G, C" plane (annual percentage increase in cars per person -- cars per person) might be preferable. An examination of post-war Great Britain data suggests that overpredictions have been the result of inappropriate parameter estimations, not model form. The Regional Hwy. Traffic Model (RHTM) car ownership model gives satisfactory short-term back-predictions, but the use of the "causal" variable "Car Purchasing Income" to achieve a time-stable model presents far greater problems in the forecasting context than the extrapolative models developed at the Transport and Road Res. Lab. Many factors affect car ownership growth and Car Purchasing Income is as much a proxy for these in the RHTM modle as time is in time-trend extrapolative models. Although converting cross-sectionally fitted causal models into predictive ones is desirable, significant problems need to be resolved. The Car Purchasing Income variable is unacceptable on theoretical grounds in that it implies car ownership decisions will be unaffected by changes in the prices of other products which might be purchased instead of a car. It is also unacceptable on practical grounds, in that immediate saturation is predicted if incomes are forecast to increase more slowly than car prices.

ELECTRONIC DIGITAL ANTI-LOCKING SYSTEM FOR PASSENGER CARS, ITS DESIGN AND OPERATION (ANTIBLOCKIERSYSTEM FUR PERSONENWAGEN MIT DIGITALER ELEKTRONIK--AUFBAU UND FUNKTION)

A passenger car antiskid system developed by Bosch, called Antiblockiersystem (ABS), prevents wheel lockup and ensures vehicle steerability and stability with shorter stopping distances than are possible with locked-wheel braking on most road surfaces. ABS consists of speed sensors, an electronic control unit, and a hydraulic unit. The front wheels are controlled separately, the rear wheels jointly. For the control process, the two variables "wheel circumferential acceleration" and "wheel slip" are used, offering an optimum brake control cycle even under unfavorable road and driving conditions. The ABS has a sophisticated monitoring feature which checks the electronic system prior to vehicle operation and the major components of the ABS in operation. Once a defect is detected, the ABS is switched off and the normal braking system is utilized.

1978 ROADSIDE VEHICLE INSPECTIONS

Results are compliled of the Bureau of Motor Carrier Safety's (BMCS) 27,601 roadside vehicle inspections conducted throughout the U.S. during 1978. The inspection program is designed to identify vehicle defects and driver conditions which could cause accidents, and to remove hazardous vehicles and drivers from the highways. Ninety-four percent (25,965) of all vehicles inspected were operated either by for-hire (authorized or exempt class), private carriers of property, or "other" carriers (e.g. transporting mail, foreign commerce carriers). Forty percent of the property-carrying vehicles were found to have one or more serious mechanical defects which resulted in the vehicle being declared out-of-service. The average number of defects per truck was 3.46 (vs. 3.31 in 1977). Most defects were found in the lighting/electrical systems. The largest number of out-of-service defects involved service brake systems. The remaining 6% of the inspected vehicles were passenger carriers (buses, authorized or exempt). The average number of defects per bus was 0.83 (vs. 1.08 in 1977). A total of 24,481 driver violations were found among the property and passenger carriers; 52% related to hours of service of drivers (mainly failure to maintain a daily log). In 1978, 1597 accidents were reported to BMCS as having been the result of a mechanical problem. These accidents resulted 124 fatalities, 1305 injuries, and $19,983,560 in property damage. The five most common defects which caused these accidents (brakes, tires, steering, wheels, and coupling devices) accounted for 31% of roadside inspection defects and resulted in 70% of out-of-service actions.

THE URBAN CAR AND ITS POWER TRANSMISSION AND SUSPENSION SYSTEMS

Size, performance, pollution level, collision damage, and energy conversion efficiency specifications for an inter-urban car of the future are outlined, and their design consequences noted. The requirements suggest an electric car with drive motors mounted on the wheels. The "conformable wheel" is proposed as a means to provide traction through the wheels. The geometry and action are described for the two-dimensional conformable wheel which consists essentially of three separate elements: a central hub capable of revolving freely about a fixed axle, a flexible outer rim or tire which is materially nonelastic and of constant length, and a number of spring-loaded telescopic spokes under compression or tension each capable of being varied in length and each hinged at one end to the hub and at the other end to the tire, with both hinge pins parallel to the axle to permit a limited degree of freedom in the wheel plane. The conformable wheel is designed to achieve traction and steering by changing the shape of the periphery. Its advantages include: no need for complicated mechanical drive joints and only little spring suspension (high degree of vehicle maneuverability), small unsprung mass, large radial movement (soft ride without the need for pneumatic tires and associated wear), simple connections between vehicle body and wheel, larger contact area between tire and ground, and very good transmission efficiency from energy source to driven wheel.

QUICK AND DIRTY VEHICLE ROUTING PROCEDURE

A vehicle routing procedure is presented for use in fleet operations where several customers are served on each route. The procedure has the following steps: estimate the number of schedules required per day (using the author's designated equation); estimate the number of vehicles needed (again, using the equation); identify any geographical barriers which may force a boundary between routes; beginning with one of the identified (or artificially created) boundaries, create a route as much like a teardrop as possible, given customer distribution and problem constraints; and immediately adjacent to this route, create another, repeating the procedure until all customers are served. Construction of routes which comply with these general rules will result in near-optimum vehicle routing operations.

TRAVEL BEHAVIOR AND THE TOTAL ACTIVITY PATTERN

Conventional aggregate and disaggregate travel models are described, and the problems associated with studying travel behavior in isolation rather than as part of the total activity pattern are noted. Travel behavior research is described which was based on an analysis of "activity diaries" filled in every quarter hour for a week for a sample of about 1100 Dutch citizens. It was found that the reported travel time averaged about 27 quarter hours per week, and the reported travel frequency about 17 trips per week (higher than that reported in other surveys). The number of reconstructed trips (unrecorded in the diaries) was about 17 trips per week. Car ownership and availability had a rather limited influence on number of trips and time spent in traveling. Trip rates were approximately the same for all degrees of urbanization. The travel pattern and activity pattern were studied separately for five categories of the sample population: working men, working women, housewives, students/school children, and others (retired people, unemployed people, etc.). Five broad activity groups were distinguished: work; housekeeping, child care, personal care, meals; shopping; study; and participation in community and cultural life, visiting, and active recreation. Substantial differences were found in activity pattern and travel behavior among the population groups. The use of the total activity pattern and time budgets per activity group as a basis for explaining individual travel behavior is indicated.

DIRECT ANALYSIS OF THE PERCEIVED IMPORTANCE OF ATTRIBUTES OF RELIABILITY OF TRAVEL MODES IN URBAN TRAVEL

In several attitudinal investigations of individual travel behavior, the reliability of the transportation system was judged to be its most important characteristic. Preliminary research is described for gaining improved understanding of the characteristics of reliability of transportation modes in urban travel. Reliability characteristics are identified; their relative importance is assessed; and an insight into possible structure of an objective reliability index is discussed. This investigation was based on perceived values of reliability, which were identified through a large attitudinal survey conducted in the Chicago metropolitan area. It was concluded that reliability of out-of-vehicle activities is more important to individuals than in-vehicle reliability. This implies that transit operators should be more concerned with arriving at the origin of a trip on time than with arriving at the destination on schedule. Finding a parking place on time is also more important than in-vehicle reliability to car users, who are more irritated with the lack of reliability of waiting time than transit users.

HEAVY GOODS VEHICLE TAXATION IN THE UNITED KINGDOM

he methods used by the British Dept. of the Environment DOE) in 1976 are examined for allocating the public costs ssociated with road provision in Great Britain among the vehi-e categories. Supplementary calculations were also carried out n more recent Dept. of Transport (DOT) estimates. It is sug-ested that the basic apportionment procedures adopted by DOE and employed in subsequent DOT policy documents tend to be sensitive to the assumptions made. These procedures appear to allocate an excessively large share of road usage costs to heavy goods vehicles (commercial trucks). Modifications to the official calculations, using alternative but at least equally sensible assumptions, suggest that the trucks are responsible for considerably less of the annual expenditure on road construction and maintenance than that determined by using the DOE (or revised DOT) formula. The high estimates of truck track costs do not automatically offer a case for lower taxation. Other types of costs, notably environmental and fuel oil foreign exchange, must be taken into account. Road taxes may also be treated as "pure taxes", levied as contributions to general government funds.

EFFECTS OF MICROWAVES ON THE PERFORMANCE OF INTERNAL COMBUSTION ENGINES. FINAL TECHNICAL REPORT

Results are presented from the first of three-phases in the research and development of an ignition/combustion assist system utilizing the principles of electromagnetics and plasma physics. The work performed included Langmuir probe studies (analysis and limitations of probes; probe measurements of propane and ethylene flames), combustion chamber studies (shape factor analysis; measurements on shapes and chokes), bomb experiment (measurement of interaction of microwave field with propagating flame front plasma), and ignition studies (analysis of conventional spark; plasma jet igniter). It was demonstrated that microwave-flame interaction is a reasonably practical and potentially attractive method of stimulating combustion to decrease vehicular exhaust pollutants and increase engine efficiency.

RESEARCH, DEVELOPMENT AND DEMONSTRATION OF NICKEL-ZINC BATTERIES FOR ELECTRIC VEHICLE PROPULSION. ANNUAL REPORT FOR 1978

The first annual report describes progress in a 33-month cooperative program between Argonne National Lab. and Gould Inc.'s Nickel-Zinc/Electric Vehicle Proj. designed to demonstrate the technical and economic feasibility of the nickel-zinc battery (Ni-Zn) for electric vehicle (EV) propulsion. The six major tasks of the program are all underway: separator development, zinc electrode development, product design and analysis, cell/module/battery testing, process development, and pilot plant mobilization. All milestones have been met. The performance of the four-cell battery module has been significant. The battery was subjected to 145 deep discharge cycles before dropping below 70% of theoretical capacity. The theoretical capacity is based on the actual amount of active nickel hydroxide, rather than on a percentage of the rated capacity. It is emphasized that since the battery was fabricated in the pilot plant and does not contain "one-of-a-kind" components, it represents production state of the art for Gould's Ni-Zn EV battery technology. Over the last several months, thermal management has been recognized as an important factor affecting Ni-Zn system performance, and work in this area is being accelerated.

FORD/DOE (DEPARTMENT OF ENERGY) SODIUM-SULFUR BATTERY ELECTRIC VEHICLE DEVELOPMENT. PHASE 1-A. FINAL REPORT

Results are summarized from analyses and design studies to evaluate the sodium-sulfur (NaS) battery, in an existing conventional production automobile, as a potential electric vehicle power source. Major sub-tasks include vehicle specifications, NaS battery packaging study, vehicle packaging layout and electrical system study. The following supporting system studies are appended: performance and economy projections; vehicle handling and safety reviews; and thermal management studies. The Ford Fiesta was chosen as the production vehicle to be modified into a two-passenger, electric test-bed vehicle powered by a NaS battery. The vehicle mission was defined to be a two-passenger, urban/suburban commuter vehicle capable of at least 100-mi range over the constant volume sampler driving cycle and a wide open throttle capability of 0 to 50 mph in 14 sec or less. Powertrain component specifications were defined, and powertrain control strategy selected. A suitable test-bed vehicle package scheme has been developed.

MOTORCYCLE ACCIDENTS IN TEENAGE MALES. A MODERN EPIDEMIC

The problem of two-wheeled motor vehicle (TWMV) accidents is discussed from the perspective of recent accident statistics for Great Britain. Accident casualties among TWMV riders have increased in contrast to a downward trend in most other road user groups. Since 1972 motorcycle rider casualties have almost doubled and moped accidents almost tripled, but a continuing steady decline in accidents has been noted for scooter riders. The 16- and 17-year-olds, mostly males, have become more heavily represented in these casualties. The exuberance and bravado of youth and a failure to appreciate hazards are cited as factors behind many of these TWMV accidents. The vast majority of such accidents in Britain occur in urban areas at intersections, involve at least one other vehicle, and occur on a dry surface. Statistics on accident circumstances are provided from a detailed survey of 425 TWMV accidents in Berkshire and Buckinghamshire during 1974. Lack of information in some other areas is recognized on psychological/sociological factors contributing to motorcycle accidents and on the role of alcohol in TWMV accidents. Various studies pertaining to the location and severity of injuries sustained in motorcycle accidents are reviewed. The recent downward trend in head injuries due to the use of crash helmets in Britain is mentioned. Various studies, particularly British, are reviewed pertaining to the medical, social, and economic consequences of motorcycle accidents. Engineering, enforcement, and education countermeasures are discussed and pertinent literature is cited.

BEHIND THE IRON CURTAIN: VEHICLE PRODUCTION RISES

Eastern European automobile, truck and bus manufacturers plan to boost their vehicle production 36% from 1978 to 1985, from 3.3 million units to 4.5 million, according to sources inside and outside the Iron Curtain. Total output in these countries is now about one-fourth of the U.S. production. Car output will rise 39% and truck production by 30%. Car registrations are expected to increase from 2.3 million in 1978 to 3.2 million in 1985, and truck registrations from one million in 1979 to 1.3 million. These figures refer to members of the Russian-controlled Council for Mutual Economic Assistance (Russia, East Germany, Poland, Czechoslovakia, Hungary, and Romania) as well as Yugoslavia. Opportunities for East-West trade will be limited by the Leninist-Marxist philosophy which dictates self-sufficiency whenever possible, a shortage of funds and especially hard currency in Eastern Europe, and the slowly declining supply of crude oil in the Soviet Bloc. Despite these obstacles, there appears to be a strong desire among many Western companies and Eastern governments to substantially expand their automotive trade. Ford Motor Co. and General Motors Corp. have established trading companies to set up barter arrangements in these Eastern European countries, confident of much greater trade in the near future. Fiat has built and equipped "turn-key" auto plants in Russia and Poland, and partially owns a Yugoslavian auto plant. U.S. automakers have declined to establish similar turn-key operations in Eastern Europe, for fear that such competitors might one day flood Free World markers with small, inexpensive cars. To support increasing Western sales, the Eastern nations are expanding their dealer organizations to provide sales, service, and parts.

SNOWMOBILE BASICS

Basic safety and driving tips are provided for the snowmobile operator. "Wind chill," the temperature effect of wind speed, is discussed, together with the proper clothing for snowmobiling, such as warm boots, helmet, tinted goggles, and insulated mitts. A wind chill chart is included. The snowmobile controls and engine are briefly described. Basic driving and handling information is provided. The three positions for the snowmobile driver are noted (seated, standing, kneeling). Some techniques for the snowmobiler are comparable to those used by the dogsledder: hopping off and working the throttle if the vehicle gets bogged down in deep or loosely-packed snow, and occasionally turning the vehicle on its side to unclog the track. Excessive speed, jumping over obstacles, and use of alcohol are discouraged. Preparations for an easy, safe ride are indicated (e.g. checking the condition of the drive belt, making sure track is clear, testing the controls, and checking the fuel), as well as safety items and spare parts to carry (spare drive belt, repair links for drive chain, pliers, flashlight, flares, first-aid kit). Carrying snowshoes is recommended in case of snowmobile breakdown.

VACUUM GAUGE: A TOP-NOTCH TROUBLESHOOTER

The vacuum gauge is a ten dollar instrument that can aid the backyard auto mechanic in diagnosing more than 30 different engine problems. Since specific engine problems affect manifold vacuum in certain ways, a vacuum gauge can accurately diagnose the engine's condition by measuring the amount and condition of engine vacuum. Sticking valves, poor rings, bad carburetor adjustments, and a leaky head gasket can be diagnosed and the positive crankcase ventilation valve system can be checked. The gauge can also be used to evaluate fuel economy. A high vacuum reading indicates a narrow throttle plate opening, and therefore increased fuel economy. Accurate, reliable readings can be obtained only from primary manifold vacuum sources; gauge manufacturer's recommendations should be followed for best results. A cranking test of the engine provides diagnostic information in terms of inches of mercury. The healthy emission-controlled engine will give a steady reading of 4 units or more; pre-1968 engines will measure 10 units or more. As the engine is running, the reading should be between 17 and 22 units, although some newer 4- and 6-cylinder models deliver acceptable performance at 15 in. An engine that gives a steady vacuum reading at idle, with the needle dropping toward zero and jumping back past 20 when the throttle is opened and closed quickly, is in good condition. Anything else indicates trouble. A permanent, dash-mounted vacuum gauge is recommended as the best way to monitor engine performance. A separate section provides a "tack up" list of safety precautions for the backyard mechanic.

LABORATORY STUDIES OF LANE OCCUPANCY SIGNS

In an evaluation of lane occupancy (lane control) signs, experimental subjects viewed and interpreted slides of conventional and novel signs. The effectiveness of each sign was determined by the speed and accuracy of the subjects' responses. The advantages of changeable message signs over fixed schedule lane occupancy signs were demonstrated by more accurate responses, quicker interpretation, and higher subject preference. The Series 3 red X and green arrows approved by the Manual on Uniform Traffic Control Devices, and the Series 4 Texas A&M design were judged more effective than the Series 2 printed message signs. The Texas A&M sign format has the additional advantage of being able to show incident messages such as "right lane closed," "closed accident," and "must turn right," in addition to the "open" and "closed" lane occupancy messages tested in this study. To reduce installation costs, it would be advantageous to display occupancy information in the highway shoulder-mounted position. It is recommended that the effectiveness of fixed schedule lane occupancy signs be examined further in field studies.

IS DELINEATION NEEDED? (ROADWAY TREATMENTS FOR GUIDING AND ADVISING MOTORISTS)

Research is reviewed concerning the effect of delineation on driving effectiveness and safety. Delineation is defined as a device or road treatment, excluding signs, that provides guidance and regulatory or warning information to a driver, including painted centerlines, raised pavement markers, postmounted delineators, guardrails, rumble strips, or fencelines. Based on the findings of research studies begun in early 1975 by the Federal Hwy. Administration, it is concluded the centerline delineation is highly cost beneficial and should be used on any paved roadway that carries two or more lanes of traffic. Delineation of the outside edge of the travel lane is also highly desirable, especially for roads wider than 6 m (20 ft). Post-mounted delineators are somewhat more effective for this application than edgelines, but both treatments are useful for roadways with high average daily traffic volumes. Delineation provides important guidance information to motorists when visibility is decreased. There is little difference in effectiveness among delineation treatments and materials, provided that they possess adequate contrast and continuity to impart a clear message to the driver. Supplemental delineation treatments to improve traffic flow for nonstandard, high-hazard situations generally result in great safety benefits. In general, wider application of conventional delineation treatments is desirable and will significantly reduce accidents.

ASSESSMENT OF THE STATE OF TECHNOLOGY OF AUTOMOTIVE STIRLING ENGINES

The current status of automotive Stirling engine technology is assessed; the engine is described and the history of its evolution is outlined. Overall engine, component, subsystem, and material problem areas are identified. Recommendations are made for further development and testing, and potential improvements are identified. Projected Stirling engine/vehicle performance is compared to that of current internal combustion engine vehicles in terms of performance, fuel consumption, multifuel capability, emissions, and noise level. Although the automotive Stirling engine is a fledgling compared to the mature internal combustion engine, it is concluded that the potential exists for achieving 1984 Stirling engine development goals. The objectives require at least a 30% reduction in fuel consumption, acceptable emissions, and satisfactory operation with a variety of alternate fuels.

AN ANALYTICAL STUDY OF ELECTRIC VEHICLE HANDLING DYNAMICS

Handling characteristics of hypothetical electric vehicle (EV) configurations were studied by applying available analytical methods. Elementary linearized models were used as well as a highly sophisticated vehicle dynamics computer simulation technique. Physical properties of specific EV's were defined for various battery and powertrain packaging approaches applied to a subcompact base car. The group of configurations gave a wide range of weight distribution and inertial properties which characterize a generic class of EV's. Computer simulations of structured maneuvers were performed for predicting handling qualities in the normal driving range and during various extreme conditions related to accident avoidance. Results consistently indicate that an EV with forward weight bias will possess handling qualities superior to one that is rear-heavy or equally balanced; the handling differences become more pronounced as yaw moment of inertia is increased. Rear-heavy EV's were found to be particularly susceptible to excessive sideslip, long response times and undesirable phase lags. Results also demonstrate the importance of properly matching tires, suspension systems, and brake system front/rear torque proportioning to a given EV configuration during the design stage. The methodology employed in this study can provide valuable guidance for developing electric (and other) vehicles with satisfactory handling qualities.

MEASURES OF EFFECTIVENESS FOR MULTIMODAL URBAN TRAFFIC MANAGEMENT. VOL. 2: DEVELOPMENT AND EVALUATION OF TSM (TRANSPORTATION SYSTEMS MANAGEMENT) STRATEGIES. FINAL REPORT

In Phase 1 of a three-phase study, hierarchical schemes of TSM (transportation systems management) strategies and tactics and comprehensive goals were developed. Measures of effectiveness (MOE's) were identified for determining degree of goal attainment through implementation of a given tactic. Data sources, field measurement procedures, and modeling techniques were identified for measuring or estimating each MOE. In Phase 2, four case studies were conducted to test and illustrate the methodology and to demonstrate the effectiveness of a variety of TSM strategies. In Phase 3, sampling and data collection procedures for some commonly used MOE's were developed. Manual and computer modeling procedures for modal split and network analysis were studied, and recommendations were developed on their applicability to TSM analyses. Study results are summarized as a guide for practicing engineers and planners who are engaged in the development and evaluation of urban area TSM plans, by providing a consistent framework for TSM strategy development, recommending measures of effectiveness for TSM strategy evaluation, and identifying and demonstrating manual and computer techniques for TSM analysis.

PARATRANSIT RESOURCE GUIDE

A guide is provided to sources of information (including personal contacts) on paratransit development at the Federal, state, and local levels, with emphasis on Federal sources and national information sources. Included are definitions of paratransit, pertinent Federal policies, and annotated introductory overview literature. Other information sources are included, such as the Transportation Res. Information Services Network and National Technical Information Service, Federal legislation, Federal agencies with contact personnel, Urban Mass Transportation Administration and Federal Hwy. Administration offices, professional organizations, consulting firms and research organizations, foreign sources of information, and a paratransit educator resource list. This guide is one element of a set of curriculum materials for university and short course instruction in paratransit. The other materials consist of five case study documents developed around a common but comprehensive analysis framework, and guides to selected readings and curriculum development.

HIGHWAY ACCIDENT REPORT. MULTIPLE-VEHICLE COLLISION IN A CONSTRUCTION ZONE, U.S. INTERSTATE 80, NEAR LARAMIE, WYOMING, AUGUST 22, 1979

At approximately 6:25 AM on 22 Aug 1979, a westbound tractor-semitrailer sideswiped an eastbound tractor-semitrailer an then struck an eastbound motorhome on a two-lane, undivide roadway in a construction zone on Interstate 80, about 30 mil northwest of Laramie, Wyo. The driver and co-driver of th westbound tractor-semitrailer were killed. Six of the seven motorhome occupants were ejected and killed; the other occupan was partially ejected and seriously injured. The two persons i the eastbound tractor-semitrailer were not injured. It was dete mined that the probable cause of the accident was the failure of the fatigued driver of the westbound truck to maintain his vehicle within the proper traffic lane. Contributing to the severity of the accident was the excessive speed of the westbound truck as it struck the eastbound truck and the motorhome at speeds of 68 and 58 mph, respectively.

NATIONAL TRANSPORTATION SAFETY BOARD. ANNUAL REPORT TO CONGRESS, 1979

Following an overview of the activities of the National Transportation Safety Board (NTSB), the accomplishments of this agency in 1979 are discussed in separate chapters on aviation, rail, highway, marine, pipeline, and hazardous materials safety. In 1979, the NTSB completed 62 major accident investigations. Field investigations numbered 1540. The Board also completed 29 foreign investigations and reviewed 3404 accident investigations conducted by other agencies. 378 safety recommendations, 8 special studies and evaluations, and 1866 statistical reports were also issued. Appended are statistical tables on accidents, accident rates, and fatalities for the various categories of air carrier service (1969 through 1979); and 1979 NTSB statistics: investigations conducted, public hearings held, accident reports adopted, special studies/investigations and safety effectiveness evaluations, and responses to proposed rulemaking.

U.S. DEPARTMENT OF TRANSPORTATION ANNUAL REPORT (NO. 12), FISCAL YEAR 1978

Activities of the Dept. of Transportation (DOT) during fiscal year 1978 are summarized in the areas of transportation policy, reorganization, energy programs, regulatory reform, marine transportation, aviation, highways, railroads, urban mass transportation, and materials transportation. Progress reports are presented for 1978 by the following DOT agencies: Office of the Secretary, Coast Guard, Federal Aviation Administration, Federal Hwy. Administration, Federal Railroad Administration, National Hwy. Traffic Safety Administration, Urban Mass Transportation Administration, Saint Lawrence Seaway Devel. Corp., and Res. and Special Programs Administration. Appended are statistical tables and graphs (1978 and other years to indicate trends) providing data on: DOT budget and personnel, Coast Guard enforcement operations and finances, commercial aviation (personnel, hijacking attempts, accidents and accident rates, fatalities, aircraft hours and miles flown, passengers carried and passenger miles flown), motor carrier safety inspection activity, train accidents and casualties, rail-highway grade crossing accidents and casualties, Alaska railroad revenue freight traffic, Amtrak (passengers, passenger miles, daily train miles, revenues, costs, deficit), motor vehicles (licensed drivers, registered vehicles, vehicle miles traveled, fatalities and fatality rate), and gas and liquid pipeline failures and casualties.

TYRE (TIRE) FACTORS AND FRONT WHEEL VIBRATIONS

An extensive survey is provided of in-plane and out-of-plane (camber and castor) tire dynamic performance. The in-plane tire response model incorporates the highly important variation of the effective rolling radius with changing tire deflection. Theoretical and experimental plots are presented for the response to fluctuations in vertical axle position and in tire radius (out-of-roundness). The out-of-plane tire model is based on the well-known taut string model. Tire mass effects have been approximated. Experimental frequency response plots show good correlation with theoretical findings. A simple front wheel suspension system showing three degrees of freedom illustrates the use of the tire model.

ANALYSIS ON CYCLE-BY-CYCLE VARIATION OF COMBUSTION FROM PRESSURE INDICATOR DATA

An indicator analyzer was developed capable of performing statistical analysis from pressure data from each cylinder of a multi-cylinder engine under steady-state conditions by use of an on-line minicomputer. This analyzer is also able to acquire engine data under transient conditions and to perform interlocutory analyses of any specified combustion cycle, utilizing an off-line large computer. Analysis on the causes of cycle-by-cycle variation of combustion was made, and a simple relationship was derived, revealing that the variance of indicated mean effective pressure may be broken down into three terms such as variances of released heat and change of internal energy and their co-variance. Experiments revealed that the variance of released heat manifests some characteristics related to the fuel supply system. The variance of change of internal energy manifests some characteristics related to the pattern of heat released in the cylinder, but the interpretation of the physical significance of the covariance term remains to be solved. This method is found to be a useful one for analyzing the causes of cycle-by-cycle variation of combustion and its improvement in actual engines.

DETERMINATION OF THE SIZE OF THE STORAGE CHAMBER AND THE CHARGING PRESSURE FOR AIR BAGS USED IN AUTOMOTIVE PASSIVE RESTRAINT SYSTEMS

A design tool is presented to predict the cylinder charge pressure and volume necessary to inflate the air bag of a passive restraint system to a given final volume and pressure. The following cases can be solved: charging pressure for a given chamber volume and desired (or specified) final pressure and volume of the bag; final bag volume and pressure for a given chamber volume and charging pressure; and design data for chamber volume, subject to bag specifications and available charging pressures. It is shown that the calculated results are independent of the elastic properties of the air bag and inflation dynamics, and that an equilibrium analysis leads to incorrect predictions.

DEVELOPMENT OF A FOUR-SPEED AUTOMATIC TRANSMISSION WITH OVERDRIVE

A new four-speed automatic transmission with overdrive, the A40D was developed and put into production by Toyota in the 1977 Crown (domestic) and the 1978 Cressida (a model exported to the U.S.). The transmission has excellent reliability and durability, small size, and low weight and cost. Clutch-to-clutch shifting between second and third gears has been improved by utilizing the direct one-way clutch in the overdrive unit. Tests and evaluation criteria of the overdrive unit and clutch-to-clutch shift have been established. Remarkable improvements in fuel economy and noise reduction have been achieved due to the numerically low overdrive gear ratio and optimum shift points.

VEHICLE STRUCTURAL ANALYSIS: A SURVEY

Attention is drawn to the increased importance of structural analysis in automotive design in the past 20 years. Structural design has advanced from the stage at which new designs were based on experience to the present stage at which detailed computer analyses have become a design tool for most new passenger car bodies. Static and dynamic analysis of integral sheet metal car bodies is discussed, as is the rapidly growing ability of structural analysis to deal with the problem of large deformations on impact. The importance of a thorough understanding of the theory of thin-walled beams in the design of ladder frames for commercial vehicles is underlined. Selected references illustrate the extent of research in vehicle structural analysis.

THE IMPACT OF FLYWHEEL-TRANSMISSIONS ON AUTOMOBILE PERFORMANCE: A LOGICAL BASIS FOR EVALUATION

Algebraic equations were evolved for evaluating the impac
flywheel-transmissions on automobile performance. These e
tions, derived from automobile power and energy balances
scribe total (laden, or fully loaded) mass and energy econom
a function of payload, range, and drive-cycle acceler
demand. Illustrative calculations were made for electric veh
(EV's) and petroleum-fueled automobiles. For EV's, the ba
peak-power capacity required as a function of the driving
tern peak-power demand was determined and was comp
with published forecasts of future battery characteristics. It
found that none of the batteries would be adequate to p
EV's through normal commuter driving patterns within the
decade, nor through normal freeway driving patterns befor
end of the century. Incorporating flywheel-transmissions w
probably enable modified EV's to follow both driving pat
For petroleum-fueled automobile and EV baseline de
simple equations were derived for allowable flywheel-tran
sion mass-fraction for breakeven total mass and breal
energy economy. The mass-fraction for breakeven total
was less than that for breakeven energy economy in pra
situations. It was less for power-determined cars (i.e. EV
ing more battery mass than needed for range requirement)
flywheel addition increased energy efficiency. It was le
range-determined cars (i.e. petroleum-fueled car carrying
battery mass than needed for power requirement) whe
payload exceeded zero. Thus, it was determined to be
difficult to reduce automobile mass than to improve e
economy by using a flywheel-transmission.

SURVEY OF LIQUID HYDROGEN CONTAINER TECHNIQUES FOR HIGHWAY VEHICLE FUEL SYSTEM APPLICATIONS

A technology-oriented survey was conducted of several recent and ongoing development and demonstration projects involving liquid hydrogen containers for fuel-system service in highway transportation systems. Following a background review, two aspects of the subject are reported: rough production-lot cost estimates for a nominal 50 gal (189 l) horizontal cylindrical container for vehicle service; and design and operational features of four different liquid hydrogen container types (developed by Beech Aircraft Corp., Boulder, Colo.; Minnesota Valley Engineering, New Prague, Minn.; Musashi Inst. of Tech., Tokyo, Japan; and Inst. of Technical Physics, Stuttgart, Germany), three of which have been used as vehicle fuel tanks. A unique, semiautomatic liquid hydrogen "service station" developed by the German institute is described. The state of technology of vehicle hydrogen containers and associated systems is assessed, including the identification of "pacing items" recommended for future research and development activities.

BUT ARE THEY SAFE DRIVERS...? (TRUCKING SAFETY)

The use of Citizens Band (CB) radio by truck drivers is discussed in terms of its negative and positive aspects. Too often CB radios are used for the truck driver's amusement (i.e. conversing with fellow truckers), thus distracting him from his task. Used properly and with courtesy, the CB can be (and often has been) a boon to both truckers and motorists in emergencies. Also discussed are truck drivers' schools. Some are fly-by-night operations with inferior curriculum and/or instruction. Many teach a trainee everthing except how to handle an emergency. Others are very comprehensive and use instructors with extensive trucking experience. Despite intensive training, it is pointed out that a minority of drivers display a callous disregard for other motorist's rights. Far too many gruesome and mindless crashes have been recorded recently which point to truck driver misjudgment.

HEAD ON. PAINTED IN SAFETY (MOTORCYCLE VISIBILITY)

Two studies are reported concerning motorcycle conspicuity, specifically the detrimental effects on visibility of small size and dark color. In view of the fact that a motorcyclist cannot change the size of his bike and is unlikely to change its color, it is recommended that fluorescent and reflectorized materials be used to increase visibility. Fluorescent materials absorb short-wavelength, nonvisible, high-energy radiation and convert it into longer wavelengths that are visible to the eye as light and color. Fluorescent strips on clothing and paint on bikes are effective safety measures. The nature of fluorescence determines its prime period of effectiveness: sunrise, sunset, and in overcast weather. At night, because of an absence of high-energy radiation, the fluorescence itself is relatively ineffective, although it is more effective than black or brown. For nighttime riding, reflectorized paint and materials are more effective. Unlike fluorescence, which transforms energy to light, reflectorization makes better use of light that is already present. For reflectorized paint to give adequate visual clues, however, it must outline the motorcycle or rider.

TROUBLESHOOTING LACK OF ENGINE POWER

Information is provided to assist the car owner in determining the cause(s) of a lack of engine power. The problem of no top-end power is caused by a linkage malfunction characterized by the throttle plates not opening to the limit of their travel. Part-throttle "bog" or a "hole" in the power curve is cited as a probable carburetor problem. Two emission control units affecting engine power are noted: the thermostatic air-cleaner assembly and the exhaust gas recirculation (EGR) system. Servicing or testing some other sources of engine power loss is discussed, including fuel filters, the EGR valve, the thermostatic air cleaner, the positive crankcase ventilation system, the fuel pump, and the electrical system. The major causes of poor engine performance are illustrated: defective vacuum advance, clogged fuel filter, bad points and condenser, poor engine timing, binding linkage, binding choke plate, damaged distributor cap, clogged fuel line, weak fuel pump, bad plugs, fouled EGR valve, and loose vacuum hose. Possible causes and their solutions are outlined in a troubleshooting chart. After making a repair, the car should be road-tested to determine if engine power has fully returned. Continued lack of engine power after repair indicates the need to replace plugs and leads.

CHILD RESTRAINT USAGE. ISSUE PAPER. REV. ED.

The issue of child restraint usage is discussed, and the National Hwy. Traffic Safety Administration's (NHTSA) position on the issue is presented. In the U.S. in 1978, 670 children under the age of five and 1160 children between the ages of five and 14 died as passengers in automobile accidents. Tens of thousands more were injured. Recent surveys have indicated that approximately 93% of children less than ten years old travel without any restraints. NHTSA encourages the states to enact legislation to require special protection for young children. This legislation should adopt Federal Motor Vehicle Safety Standard 213-80 for child-passenger protective devices, should encourage proper conformance to manufacturers' instructions on proper usage, and should require the use of such devices whenever children ride in motor vehicles. States are encouraged to conduct aggressive public information and education programs to increase the public's awareness of the need to use child restraints. Loan-a-seat distribution programs are recommended (instructions for implementation appended) and suggestions are provided for inclusion in media and educational programs.

GENERAL SAFETY BELT USAGE. ISSUE PAPER. REV. ED.

The issue of general safety belt usage is discussed, and the National Hwy. Traffic Safety Administration's (NHTSA) position on the issue is presented. Recent surveys suggest that safety belt usage in the U.S. has dropped from 20% in the mid-1970's to only 14% by the end of 1978. NHTSA believes that the most immediate need is to establish a program in each state to get maximum visibility for the restraint issue. This program should make extensive use of existing organizations such as medical groups, highway safety groups, safety councils, civic groups, educational and health groups, and driver education and improvement organizations. Individual state and local workshops should develop and implement a comprehensive occupant restraint plan, beginning with a coordinated media and educational effort focusing particularly on child/infant restraint. Grassroots organizations should be encouraged and their efforts monitored and coordinated with state efforts. Representation at NHTSA follow-up workshops should be from a wide range of groups. Restraint programs using Section 402 funds should include an evaluation plan.

HIGHWAY SAFETY DATA. A REPORT TO THE SECRETARY OF TRANSPORTATION BY THE NATIONAL HIGHWAY SAFETY ADVISORY COMMITTEE

Results are presented of an investigation of the quality, quantity, and timeliness of data on highway safety available to Federal and state highway safety personnel. Coordination is recommended between the data interests of the National Hwy. Traffic Safety Administration and the Federal Hwy. Administration where feasible. Data requests made at the Federal level should be reviewed by knowledgeable public people, such as those who reviewed the National Accident Sampling System (NASS) project. A group of people knowledgeable in accident data and their collection, representing Federal, state, and public interests, should be assembled to make recommendations on the needs and funding of state and Federal highway safety data systems. Until action is taken to resolve the status of data support for the state and Federal activities, it is recommended that the Federal agen-
cies continue to work with the states to help them develo
needed data systems, and that NASS continue to be implemen
ed as the major source of data. An inventory list of accide
data collection projects is appended.

55 MPH IMPACT PROGRAM EVALUATION. PHASE 1 SUMMARY REPORT

A pilot test was conducted in Connecticut of the procedures, instrumentation, and methods to be employed in an overall demonstration project to assess the relationship between levels of police patrol strength on limited access highways and motorists' compliance with the fifty-five miles per hour speed limit. The speed-measuring equipment, the utility of data collection procedures and forms, and the scheduling of enforcement patrols are described. Summary data are presented on the enforcement activities of baseline and increased patrol level periods. Problems encountered in Phase 1 included managerial and operational problems, as well as those in data acquisition, sensor performance, and conditions unrelated to the program (gasoline shortage, trooper strike). Recommendations are made for conducting Phase 2, the overall demonstration which will involve Connecticut and other localities.

SOCIAL CONSEQUENCES OF ACCIDENTS. FINAL REPORT

A study was undertaken to interview seven seriously injured traffic victims and their families and to have them describe, in their own words, the long term personal and social consequences (financial, psychological, and family) of serious traffic accidents. There was a great deal of difficulty in contacting suitable informants. Access to medical records would be an important help in future studies. These medical records would provide a more valid assessment of physical trauma and a more reliable means of contacting victims who have moved since the accident. The Abbreviated Injury Scale (AIS) and the Injury Severity Score (ISS) are poor and inadequate indicators of the long term personal and social consequences that result from serious traffic injuries. In fact, the victim with the lowest ISS rating appeared to suffer the most severe consequences from her injury. A fatalistic attitude toward the use of seat belts was noted. Recommendations for future studies include the effects of spinal cord injuries, independent interviews with other family members, and provisions of additional information on the age, sex, and occupation of the accident victim to supplement AIS ratings.

RULES OF THE ROAD RATED

An annual rating of state traffic laws for 1978 is presented to compare these laws with rules of the road contained in the Uniform Vehicle Code (UVC) as of January 1, 1979. Uniform rules are important in highway safety, and substantial improvement in uniformity and termination of archaic or unreasonable laws are needed to improve the safe and efficient use of highways. Based on ratings of the 50 states, the District of Columbia, and Puerto Rico, it is clear that no state traffic code duplicates every rule of the road, although the number of laws differing from the UVC has been steadily decreasing since 1969. Six states (Connecticut, Indiana, Kentucky, Louisiana, South Carolina, and Utah) made substantial progress toward uniform traffic laws in 1978. The most important single improvement in 1979 was Connecticut's adoption of a rule requiring drivers to yield to pedestrians in crosswalks. The UVC rule limiting the use of alternately flashing red lights on school buses to situations where a bus has stopped has not gained universal acceptance. Of the differences between state traffic laws and the UVC, almost 45% involve traffic control devices and right of way. This difference is too high. A summary table of data on state traffic laws and tables for each article in Chapter 11 of the UVC are appended.

STATES' MODEL MOTORIST DATA BASE. DATA ELEMENT DICTIONARY FOR TRAFFIC RECORDS SYSTEMS

Common names, abbreviations, definitions, uses, sources, synonyms, and representations of data elements transmitted and communicated by state and local traffic record systems are provided in a dictionary intended to promote uniformity in the transmission of traffic records. In the areas of motor vehicle registration, driver licensing, highways, accidents, financial responsibility, motor vehicle inspection, commercial vehicle reciprocity, traffic law enforcement, and emergency medical services, the dictionary is designed to facilitate quick location of desired information. Its use does not require maintenance of all data elements or items, and the dictionary does not standardize any data base design, file structure, or internal storage method. With the aid of standard message structures and protocols, data can be rapidly interchanged by jurisdictions to improve operational functions. Provision has been made for annual amendments to the dictionary. A glossary defines some terms used frequently in the State's Model Motorist Data Base Dictionary. A guide to the use of the Data Element Dictionary, references, and an index are included. An appendix notes data elements by technical subcommittee responsibility.

A COMPARISON OF ALCOHOL INVOLVEMENT IN PEDESTRIANS AND PEDESTRIAN CASUALTIES. FINAL REPORT

A study was undertaken to determine the frequency of alcohol involvement in adult (14 years and over) pedestrian fatalities and injuries; to determine if alcohol was over-represented; to identify the causal role of alcohol; and to suggest countermeasures. Pedestrian fatalities were sampled using data from the New Orleans, La., coroner; nonfatal pedestrian victims were sampled based on information supplied by a large New Orleans hospital; and crash and control data were gathered via followup interviews, roadside interviews, and police files. Results showed that 50% of fatal and nonfatal pedestrian victims had been drinking. About 50% of those who had been drinking had blood alcohol concentrations (BAC's) of 0.20% or higher. Victims were compared to three distinct control groups. The most conservative group, with age and sex matched at the accident site, showed that relative risk of an accident increased markedly at a BAC of 0.20% or more. The least conservative group showed that relative risk increased markedly at a BAC of 0.10% or more. Alcohol-involved pedestrians were more often middle-aged males, struck at night and on weekends, who exhibited various social and personal problems. Common accident types were "dart and dash," "pedestrian strikes vehicle," and "not classifiable." It is concluded that pedestrian drinking is a major factor in adult pedestrian-vehicle crashes. Legal, educational, engineering, and rehabilitation countermeasures are discussed. Appendixes contain study instruments, supporting data, and legal opinion concerning the admissibility into evidence of collected blood alcohol data. An addendum by the National Hwy. Traffic Safety Administration states that none of the recommended countermeasures is currently ready for implementation, since none has been field tested or examined for feasibility or cost-effectiveness.

MOTORCYCLE OPERATOR LICENSING. ISSUE PAPER

Growth in motorcycle use and increased accidents, injuries, and fatalities are the focus of this issue paper. In light of public concern about gasoline shortages and price increases, consumers are turning to motorcycles as an alternative transportation mode. Motorcycles sales increased by 10%-15% and registrations increased about 4% in 1979. Motorcycle fatalities exceeded 4,800 during the year. A 1968 study by the Airborne Instruments Laboratory concluded that motorcycle operator testing and licensing offered the best long-range and cost-effective accident countermeasure. A 1973 research effort by the Motorcycle Safety Foundation defined knowledge and skills needed by motorcyclists to drive safely. During 1975, the National Hwy. Traffic Safety Administration (NHTSA) funded research in the development of a model motorcycle operators' manual, knowledge tests, and an off-street skills test. These were used in California's Improved Motorcyclist Licensing and Testing Project. The motorcycle off-street skills test (MOST) consists of nine subtests: starting and accelerating on a hill; making sharp turns; turning control (right and left at normal speed); stopping judgment; turning speed judgment; making a quick stop (straight and on a curve); and obstacle avoidance. The motorcycle operators' manual provides applicants with information on basic preriding cycle inspection, rider protective gear, dealing with dangerous road surfaces, and handling on-street emergency situations. The motorcycle in-traffic test of license applicant ability uses uniform forced-choice scoring criteria. Technical, training, and support assistance is available to states desiring to implement motorcycle operator licensing programs from the NHTSA and the Motorcycle Safety Foundation. Improved testing
licensing of motorcycle operators is an essential element of
comprehensive state motorcycle safety program.

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 2. FINAL TECHNICAL REPORT

The problem of identifying and selecting superior energy-absorbing materials for school bus interiors was addressed in a study program designed to develop material selection criteria, to identify and select superior energy-absorbing materials currently on or nearing the market, and to verify material selections using established criteria. Material selection pass/fail criteria were developed in the areas of flammability, smoke emissions, toxicity, energy absorption, shock attenuation, torso impacts, facial impacts, head impacts, knee impacts, general design, producibility, cost and weight, maintainability and environmental durability, and resistance to vandalism. Screening of candidate padding cover and core materials was performed, based on three factors: high-temperature performance; physical characteristics important from the standpoint of padding design; and material cost. Mild steel alloy and Kydex 100, an acrylic polyvinyl chloride compound, were found to be good to excellent cover materials. Favorable core materials were low-smoke Neoprene and paper honeycomb. A set of preferred materials was tested experimentally to verify their compliance with these criteria. The tests included flammability, dynamic drop, and sled impact tests.

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 3. APPENDICES. FINAL REPORT

Supplementary information is provided for a report on the identification and selection of superior energy-absorbing materials for school bus interiors. Material selection criteria consider high-temperature performance (ignitability, flame spread, smoke emissions, and toxicity), shock attenuation (compliance with injury criteria), energy absorption, and general design (cost and weight effectiveness and environmental and vandal resistiveness). The information includes a state-of-the-art review of the design of bus interior padding systems; a copy of Federal Motor Vehicle Safety Standard No. 302 test standards for flame spread, ignitability and emissions; and results of flammability, drop, and sled tests.

FINAL REGULATORY ANALYSIS OF THE MODEL YEAR 1982 LIGHT TRUCK FUEL ECONOMY STANDARDS

Fuel economy standards for model year (MY) 1982 light trucks are examined (background, assumptions, microeconomic and macroeconomic analysis, alternatives, and issues). Effects of the final rule for MY 1982 light trucks, in comparison to light trucks meeting MY 1981 standards, are: lifetime fuel savings (128,195 miles), 1.2 billion gallons; average estimated retail price increase, $95 per vehicle; present value of operating cost savings, $470 per vehicle; net consumer benefits, $375 per vehicle; and industry investment requirements, $900 million. This final rule sets average fuel economy standards at 18 mpg for two-wheel drive light trucks and at 16 mph for four-wheel drive trucks. Vehicles subject to the rule include pickup trucks, vans, and general utility vehicles weighing 8,500 pounds gross vehicle weight or less, having a curb weight of 6,000 pounds or less, and having a frontal area of 45 square feet or less. It is projected that except for Chrysler Corp., all manufacturers will be able to meet the standards and have plans to exceed the standards. Appended are technology costs and capital expenditures incurred by manufacturers.

ACTS ADMINISTERED BY THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION. REV. ED., MARCH 1980

Provisions of three acts administered by the National Hwy. Traffic Safety Administration are detailed. The Highway Safety Act of 1966 defines the authority of the Secretary of Transportation and contains sections dealing with highway safety programs, highway safety research and development, duties of the National Hwy. Safety Advisory Committee, school bus driver training, and innovative project grants. The motor Vehicle Information and Cost Savings Act focuses on bumper standards, automobile consumer information, diagnostic inspection demonstration projects, odometer requirements and improvement of automotive efficiency (fuel economy). The National Traffic and

Motor Vehicle Safety Act of 1966 is concerned with motor vehicle safety standards (including notification and remedy of defects), tire safety, research and test facilities, and establishment of a national driver register.

THE U.S. DEPARTMENT OF TRANSPORTATION SURVEYS ON SAFETY BELT USE AND THEIR COMFORT AND CONVENIENCE. FACT SHEET

Two studies dealing with safety belt use in relation to comfort and convenience were designed to determine the rate of safety belt use in the United States and to examine differences among various seat belt systems in 1980 vehicles in terms of comfort, convenience, and ease of use. In the belt use study, observations of more than 150,000 drivers were made at traffic intersections in 19 metropolitan areas during the Nov 1977-Dec 1979 period. Using observations of more than 16,000 cars between July-December 1979, the study also examined passenger car occupancy rates and restraint use by age category. In the comfort and convenience study, 115 participants selected from among licensed drivers in the Detroit metropolitan area were asked to rate seat belts according to accessibility, extending, buckling, fit, pressure, releasing, and retracting. Belt systems in 36 vehicles were also evaluated for compliance with the National Hwy. Traffic Safety Administration requirements for comfort and convenience. Belt use by drivers averaged 14.1%, 13%, and 10.9% for 1977, 1978, and 1979, respectively. Automatic belts were used more than manual belts. Use rates were higher for women than men. Among late model cars, use was highest for subcompact cars, next highest for compact cars, and lowest for intermediate and full-size cars. Use was higher in newer foreign cars than in U.S. models, higher on turnpikes than other roads, and slightly higher during the day than at night. For infants one year old or less, restraint use, both incorrect (23%) and correct (22%), was highest; children aged one to four had the lowest seat belt use. The greatest problem in comfort and convenience was latch plate accessibility, followed by problems in extending the latch plate, belt fit, belt pressure, and buckling. Factors in safety belt use were vehicle size, manufacturer, road type, geographic area, city, sex, income, and safety consciousness (head restraint use). Also noted are safety belt compatibility problems with child restraints.

THE CAR BOOK: A CONSUMER'S GUIDE TO CAR BUYING

Information is tabulated for 20 subcompact, 16 compact, 25 intermediate, and 20 large cars, both foreign and domestic, on the following main topics: safety, fuel economy, maintenance, and insurance. A purchasing guide rates each vehicle on crash test results; safety belt comfort and convenience; fuel economy; and costs of preventive maintenance, general and accident repair, and insurance. The safety section covers crash test results, fatality rates, child seats, and safety belts. Factors affecting fuel economy are briefly discussed. Comparative maintenance costs are tabulated for 9 components and preventive maintenance, then rated relatively. The tire grading system and t
buying are discussed. Insurance and accident costs, includi
discounts and surcharges are given. Steps to resolve complai
are outlined, and using the hotline explained. Used car buyi
tips are given, and safety recalls in 1977-1980 are tabulated
make and model for 11 automotive systems. Brief discussions
the Research Safety Vehicle, automatic safety belts, and air b
are included. A buyer's checklist is provided, as are names
addresses of Federal agencies having automobile programs
presidents of the major automobile manufacturers.

VEHICLE SAFETY IN THE WORLD CAR MARKETPLACE. REMARKS BEFORE THE WORL MOTOR INDUSTRY CONFERENCE, GENEVA, SWITZERLAND, MARCH 3, 1980

Trends in the automotive industry are examined, with refere
to motor vehicle accidents and safety measures. Although
economy seems to have the highest priority, safety is an equ
important market issue. In the U.S., motor vehicle accidents
50,000 people a year, and represent the leading cause of de
and disfiguring injury among young people. The automo
industry has been slow to adopt a "preventive engineer
approach and blames government for many of its difficul
Instead of favoring foreign competition in the U.S., Federal
economy standards are making U.S. companies more com
tive at home and abroad in their products and producti
Under the pressure of these standards, automobile manufactu
are combining advantages of American cars with improved
economy, lower emissions and some increase in safety. C
testing of new vehicles is described. The immediate challeng
manufacturers is fuel economy; by 1985, it is expected tha
million gallons of fuel per day will be saved through mil
improvements. Areas where competitive innovation can be
plied are styling, electronics, design of trouble-free cars,
occupant safety. The market potential of safety is discusse
connection with the Res. Safety Vehicle (RSV) and safety i
vations by automobile manufacturers: foam-filled steel struc
(RSV), air bags, passive belts, three point belts, more c
worthy structures, antilock brakes, computer diagnosis
warning systems, "soft" front bumpers, and run-flat tires.

REMARKS BEFORE THE NATIONAL ASSOCIATION OF FLEET ADMINISTRATORS, NEW ORLEANS, MARCH 10, 1980

Technology developments in the motor vehicle industry
related safety legislation are explored. There is increasing r
nition that benefits of technology are not without concom
costs. In 1979, traffic deaths totaled over 50,000, the fifth
ing cause of death in the U.S. The annual cost of motor ve
accidents, including lost productivity, medical bills, and i
ance payments, is reaching $50 billion. The General Accou
Office estimates that motor vehicle safety standards in

through 1974 saved more than 28,000 lives. When this annual rate is projected through 1979, it is estimated that about 64,000 lives were saved. Federal fuel economy standards are significant. Requirements for passenger automobiles through model year 1985 and for light trucks through model year 1981 correspond to a saving of 220 billion gallons of gasoline between 1978 and 1990 (savings of $60 billion in imported fuel costs). Fuel economy and safety goals sometimes conflict, but research indicates that technology is available to reduce more highway deaths and injuries without sacrificing fuel economy. The Motor Vehicle Information and Cost Savings Act has created several programs to help consumers. Among these are consumer information standards on uniform tire quality grading, and vehicle crashworthiness, susceptibility to damage, and cost of repair. Crash tests of new vehicles are described (film). Future requirements of automatic restraint systems are outlined. Cooperation of vehicle fleet operators is solicited.

REMARKS AT THE SPRING MEETING OF THE D.C. CHAPTER OF THE AMERICAN ACADEMY OF PEDIATRICS, WASHINGTON, D.C., MARCH 25, 1980

The use of child restraint devices to reduce deaths and injuries to children traveling in motor vehicles is addressed. Cars are not designed for young children, and they frequently do not accomodate standard child restraint devices. Many improvements are needed, such as elimination of protruding knobs and surfaces from the lower dashboard, the exterior, and elsewhere in the vehicle. Any child safety seat sold in the United States should fit any automobile, and automobile seat belts should be long enough to accomodate any child restraint; tether anchorages or predrilled holes for easy installation should be installed in every car manufactured; inertial reels in the front passenger position should have locking mechanisms for the safe installation of child restraints; and cargo compartments in all vehicles should be made inaccessible to children crawling from the back seat. Since about 90% of parents do not provide proper child restraint devices to compensate for safety shortcomings in automobiles, it is estimated that about 2000 children under 14 years of age will die in automobile accidents during 1980 and that 90,000 will be injured seriously enough to require hospital admission or treatment. Most injuries will be to the head and face. Factors in the use of child restraint devices are examined, and Federal efforts to upgrade child seating systems (crash testing) are reviewed. The need to educate health professionals and consumers about motor vehicle safety is emphasized, and methods to accomplish this are enumerated.

PROPOSED AMENDMENTS TO TITLE V OF THE MOTOR VEHICLE INFORMATION AND COST SAVINGS ACT. STATEMENT BEFORE THE SUBCOMMITTEE ON ENERGY AND POWER, HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE, MARCH 28, 1980

Testimony was presented regarding proposed amendments to Title V of the Motor Vehicle Information and Cost Savings Act. Title V requires the Secretary of Transportation to set corporate average fuel economy standards for passenger cars and light trucks. Projected cumulative passenger car fuel savings from model year 1978 through model year 2000 will approximate 395 billion gallons. Comparable fuel savings for light trucks are estimated to be about 114 billion gallons. Both government and consumer cost savings due to fuel economy standards are significant. In its evaluation of the standards, the National Hwy. Traffic Safety Administration recommends certain changes: to exempt passenger cars and light truck manufacturers producing fewer than 10,000 vehicles per year; to allow manufacturers to average U.S. assembled automobiles with their imports if U.S. production was initiated before the Act; to allow credits earned by manufacturers to be carried forward or backward for three years instead of the current one year; and to exempt manufacturers from a finding of unlawful conduct for their failure to comply with fuel economy standards if they have earned sufficient credits in the three years before the penalty year to offset such a penalty. Low-volume manufacturers are noted in an appendix.

DIAGNOSTICS
DIAGNOSTICS OF GEAR ASSEMBLY--A NEW APPROACH USING IMPACT ANALYSIS
HS-028 395

DICTIONARY
STATES' MODEL MOTORIST DATA BASE. DATA ELEMENT DICTIONARY FOR TRAFFIC RECORDS SYSTEMS
HS-805 226

DIDN
CONSPICUITY. HOW TO SURVIVE THE "I DIDN'T SEE HIM" SYNDROME (MOTORCYCLIST VISIBILITY)
HS-027 49

DIESEL
DESIGN AND FATIGUE LIFE EVALUATION OF PISTONS FOR HIGH BMEP (BRAKE MEAN EFFECTIVE PRESSURE) DIESEL ENGINES
HS-027 43

DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION
HS-027 43

DIESEL ENGINE DESIGN CONCEPTS FOR THE 1980'S
HS-027 51

DIESEL ENGINE MANUFACTURING IN THE 1980'S
HS-027 51

DIESEL ENGINE THERMAL LOADING
HS-027 42

DIESEL-STIRLING COMBINATION MAY IMPROVE EFFICIENCY
HS-027 50

EFFECT OF PARTIAL SUPPRESSION OF HEAT LOSS TO COOLANT ON THE HIGH OUTPUT DIESEL ENGINE CYCLE
HS-027 42

EXPERIMENTAL INVESTIGATION OF THE INSTANTANEOUS HEAT TRANSFER IN THE CYLINDER OF A HIGH SPEED DIESEL ENGINE
HS-027 431

HEAT TRANSFER IN THE INDIRECT DIESEL ENGINE
HS-027 430

PREDICTION OF THERMAL LOADING OF SUPERCHARGED DIESEL ENGINES
HS-027 42

SOME DIESEL PISTON FEATURES IN DESIGN ANALYSIS AND EXPERIMENT
HS-027 434

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

DIFFICULT
THE DIFFICULT AGE (SAFETY RESTRAINTS FOR CHILDREN)
HS-027 422

DIGITAL
ELECTRONIC DIGITAL ANTI-LOCKING SYSTEM FOR PASSENGER CARS, ITS DESIGN AND OPERATION (ANTIBLOCKIERSYSTEM FUR PERSONENWAGEN MIT DIGITALER ELEKTRONIK--AUFBAU UND FUNKTION)
HS-028 519

DIGITALER
ELECTRONIC DIGITAL ANTI-LOCKING SYSTEM FOR PASSENGER CARS, ITS DESIGN AND OPERATION (ANTIBLOCKIERSYSTEM FUR PERSONENWAGEN MIT DIGITALER ELEKTRONIK--AUFBAU UND FUNKTION)
HS-028 519

DIMENSION
SHOT PEENING--AN ADDED DIMENSION
HS-027 509

DIMENSIONAL
STRENGTH ANALYSIS OF THERMALLY LOADED ENGINE COMPONENTS BY TWO-DIMENSIONAL AND THREE-DIMENSIONAL FINITE ELEMENT MODELS
HS-027 425

DIMMING
"TOWN BEAMS" FOR VEHICLES--EXPERIENCE WITH AN AUTOMATIC HEADLAMP DIMMING SYSTEM
HS-027 490

DIRECT
DIRECT ANALYSIS OF THE PERCEIVED IMPORTANCE OF ATTRIBUTES OF RELIABILITY OF TRAVEL MODES IN URBAN TRAVEL
HS-028 525

DIRTY
QUICK AND DIRTY VEHICLE ROUTING PROCEDURE
HS-028 523

DISAGGREGATE
AN APPRAISAL OF AGGREGATE AND DISAGGREGATE CAR OWNERSHIP FORECASTING METHODS
HS-028 518

DISCRIMINATION
BLOOD ALCOHOL LEVEL DISCRIMINATION BY ALCOHOLICS: THE ROLE OF INTERNAL AND EXTERNAL CUES
HS-027 477

DISSECTION
SEAT BELT AORTA: ACUTE DISSECTION AND THROMBOSIS OF THE ABDOMINAL AORTA
HS-028 502

DISTANCE
SCALING PERCEIVED DISTANCE ALONG A ROAD
HS-027 478

DISTRIBUTION
DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION
HS-027 432

DOE
FORD/DOE (DEPARTMENT OF ENERGY) SODIUM-SULFUR BATTERY ELECTRIC VEHICLE DEVELOPMENT. PHASE 1-A. FINAL REPORT
HS-028 529

DOT
IMPACT OF HELMET LAW REPEAL. REPORTS GIVEN ON DOT (DEPARTMENT OF TRANSPORTATION) 4-STATE MOTORCYCLE HELMET STUDY
HS-027 451

DRAG
AN APPLICATION OF EQUATION ERROR IDENTIFICATION TECHNIQUES TO THE PROBLEM OF VEHICULAR DRAG PARAMETER DETERMINATION
HS-027 466

DETERMINATION OF VEHICLE ROLLING RESISTANCE AND AERODYNAMIC DRAG
HS-027 465

DRINKING
ARKANSAS MOTORISTS: OPINIONS AND ATTITUDES ABOUT DRINKING, DRIVING AND ENFORCEMENT OF RELATED LAWS
HS-027 486

DRIVER
DRIVER EDUCATION EVALUATION TESTS. SUMMARY REPORT
HS-028 380

DRIVER EYE HEIGHT: A FIELD STUDY
HS-027 492

DRIVERS
BUT ARE THEY SAFE DRIVERS...? (TRUCKING SAFETY)
HS-028 551

TRAFFIC ACCIDENTS INVOLVING PSYCHIATRIC PATIENTS. CHARACTERISTICS OF ACCIDENTS INVOLVING DRIVERS WHO HAVE BEEN ADMITTED TO DANISH PSYCHIATRIC DEPARTMENTS
HS-027 413

DRIVING
ARKANSAS MOTORISTS: OPINIONS AND ATTITUDES ABOUT DRINKING, DRIVING AND ENFORCEMENT OF RELATED LAWS
HS-027 486

PERCEPTUAL/COGNITIVE SKILLS AND DRIVING: EFFECTS OF BRAIN DAMAGE
HS-028 396

DRUG
TREATMENT IN AN ALCOHOLISM AND DRUG ADDICTION UNIT
HS-027 416

DRUGS
ROAD ACCIDENTS: ARE DRUGS OTHER THAN ALCOHOL A HAZARD?
HS-027 444

DUPLICATION
LONG LIFE RANDOM FATIGUE BEHAVIOR OF NOTCHED SPECIMENS IN SERVICE, IN SERVICE DUPLICATION TESTS, AND IN PROGRAM TESTS
HS-028 393

DYNAMICS
AN ANALYTICAL STUDY OF ELECTRIC VEHICLE HANDLING DYNAMICS
HS-028 537

ECONOMETRIC
CONSUMERS' RESPONSES TO FUEL-EFFICIENT VEHICLES: A CRITICAL REVIEW OF ECONOMETRIC STUDIES
HS-027 438

ECONOMY
FINAL REGULATORY ANALYSIS OF THE MODEL YEAR 1982 LIGHT TRUCK FUEL ECONOMY STANDARDS
HS-805 291

POLICY CONFLICT--ENERGY, ENVIRONMENTAL, AND MATERIALS: AUTOMOTIVE FUEL-ECONOMY

STANDARDS' IMPLICATIONS FOR MATERIALS. REPORT TO THE CONGRESS OF THE UNITED STATES
HS-028 516

VEHICLE FUEL ECONOMY REVIEW
HS-027 499

EDUCATION
DRIVER EDUCATION EVALUATION TESTS. SUMMARY REPORT
HS-028 380

EFFECTIVE
DESIGN AND FATIGUE LIFE EVALUATION OF PISTONS FOR HIGH BMEP (BRAKE MEAN EFFECTIVE PRESSURE) DIESEL ENGINES
HS-027 433

EFFECTIVENESS
MEASURES OF EFFECTIVENESS FOR MULTIMODAL URBAN TRAFFIC MANAGEMENT. VOL. 2: DEVELOPMENT AND EVALUATION OF TSM (TRANSPORTATION SYSTEMS MANAGEMENT) STRATEGIES. FINAL REPORT
HS-028 538

THE EFFECTIVENESS OF ACCREDITED TRAFFIC VIOLATOR SCHOOLS IN REDUCING ACCIDENTS AND VIOLATIONS
HS-028 387

EFFICIENCY
DIESEL-STIRLING COMBINATION MAY IMPROVE EFFICIENCY
HS-027 506

EFFICIENT
CONSUMERS' RESPONSES TO FUEL-EFFICIENT VEHICLES: A CRITICAL REVIEW OF ECONOMETRIC STUDIES
HS-027 438

EFFORTS
CALIFORNIA'S SAFETY EFFORTS--PAST AND PRESENT (HIGHWAY CONSTRUCTION AND MAINTENANCE ZONES)
HS-027 493

EINFLUSS
EFFECT OF WHEEL SUSPENSION TYPES ON WHEEL LOAD AND SIDE FORCES (EINFLUSS DER RADAUFHANGUNG AUF RADLASTEN UND SEITENKRAFTE)
HS-028 509

ELECTRIC
A.C. (ALTERNATING CURRENT) MOTOR CONTROL FOR ADVANCED ELECTRIC VEHICLES
HS-028 507

AN ANALYTICAL STUDY OF ELECTRIC VEHICLE HANDLING DYNAMICS
HS-028 537

FORD/DOE (DEPARTMENT OF ENERGY) SODIUM-SULFUR BATTERY ELECTRIC VEHICLE DEVELOPMENT. PHASE 1-A. FINAL REPORT
HS-028 529

RESEARCH, DEVELOPMENT AND DEMONSTRATION OF NICKEL-ZINC BATTERIES FOR ELECTRIC VEHICLE PROPULSION. ANNUAL REPORT FOR 1978
HS-028 528

TESTING A PROTOTYPE INDUCTIVE POWER COUPLING FOR AN ELECTRIC HIGHWAY SYSTEM
HS-027 456

15 KWE (NOMINAL) SOLAR THERMAL ELECTRIC POWER CONVERSION CONCEPT DEFINITION STUDY--STEAM RANKINE TURBINE SYSTEM. FINAL REPORT
HS-027 483

15 KWE (NOMINAL) SOLAR THERMAL-ELECTRIC POWER CONVERSION CONCEPT DEFINITION STUDY--STEAM RANKINE RECIPROCATOR SYSTEM. FINAL REPORT
HS-027 484

ELECTRICAL
IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

ELECTRONIC
ELECTRONIC CONTROL UNIT FOR PASSENGER CAR ANTISKID
HS-027 458

ELECTRONIC DIGITAL ANTI-LOCKING SYSTEM FOR PASSENGER CARS, ITS DESIGN AND OPERATION (ANTIBLOCKIERSYSTEM FUR PERSONENWAGEN MIT DIGITALER ELEKTRONIK--AUFBAU UND FUNKTION)
HS-028 519

HIGH QUANTITY, LOW COST, HIGH ENVIRONMENT AUTOMOTIVE TRANSDUCERS, A NEW BREED FOR USE IN ADVANCED AUTOMOTIVE ELECTRONIC SYSTEMS
HS-027 461

THE TRUCK ELECTRONIC GOVERNOR SYSTEM
HS-027 464

THE 80S. STANDARDS FORCE MOVE TO ELECTRONIC ENGINE CONTROLS
HS-027 437

ELECTRONICS
IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

ELEKTRONIK
ELECTRONIC DIGITAL ANTI-LOCKING SYSTEM FOR PASSENGER CARS, ITS DESIGN AND OPERATION (ANTIBLOCKIERSYSTEM FUR PERSONENWAGEN MIT DIGITALER ELEKTRONIK--AUFBAU UND FUNKTION)
HS-028 519

ELEMENT
STATES' MODEL MOTORIST DATA BASE. DATA ELEMENT DICTIONARY FOR TRAFFIC RECORDS SYSTEMS
HS-805 226

STRENGTH ANALYSIS OF THERMALLY LOADED ENGINE COMPONENTS BY TWO-DIMENSIONAL AND THREE-DIMENSIONAL FINITE ELEMENT MODELS
HS-027 425

ENERGY

APPROACH TO ASSESSING THE IMPACT OF ENERGY CONSERVATION POLICIES ON TRANSPORTATION DEMAND
HS-028 511

ENERGY CONSERVATION POTENTIAL OF OFF-HIGHWAY RECREATIONAL MOTOR VEHICLE. REPORT TO THE CONGRESS
HS-028 392

ENERGY INTENSITY AND RELATED PARAMETERS OF SELECTED TRANSPORTATION MODES: PASSENGER MOVEMENTS
HS-027 441

ENERGY POLICY IMPACT EVALUATION
HS-028 510

FORD/DOE (DEPARTMENT OF ENERGY) SODIUM-SULFUR BATTERY ELECTRIC VEHICLE DEVELOPMENT. PHASE 1-A. FINAL REPORT
HS-028 529

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 1. FINAL SUMMARY REPORT
HS-805 270

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 2. FINAL TECHNICAL REPORT
HS-805 271

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 3. APPENDICES. FINAL REPORT
HS-805 272

POLICY CONFLICT--ENERGY, ENVIRONMENTAL, AND MATERIALS: AUTOMOTIVE FUEL-ECONOMY STANDARDS' IMPLICATIONS FOR MATERIALS. REPORT TO THE CONGRESS OF THE UNITED STATES
HS-028 516

PROPOSED AMENDMENTS TO TITLE V OF THE MOTOR VEHICLE INFORMATION AND COST SAVINGS ACT. STATEMENT BEFORE THE SUBCOMMITTEE ON ENERGY AND POWER, HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE, MARCH 28, 1980
HS-810 370

SURVEY AND ANALYSIS OF ENERGY INTENSITY ESTIMATES FOR URBAN TRANSPORTATION MODES
HS-028 512

ENFORCEMENT

ARKANSAS MOTORISTS: OPINIONS AND ATTITUDES ABOUT DRINKING, DRIVING AND ENFORCEMENT OF RELATED LAWS
HS-027 486

ENGINE

COMPUTERS IN ENGINE DESIGN
HS-027 518

DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION
HS-027 432

DIESEL ENGINE DESIGN CONCEPTS FOR THE 1980'S
HS-027 516

DIESEL ENGINE MANUFACTURING IN THE 1980'S
HS-027 517

DIESEL ENGINE THERMAL LOADING
HS-027 423

EFFECT OF PARTIAL SUPPRESSION OF HEAT LOSS TO COOLANT ON THE HIGH OUTPUT DIESEL ENGINE CYCLE
HS-027 427

ENGINE TECHNOLOGY FOR THE 1980'S. ENGINEERING KNOW-HOW IN ENGINE DESIGN, PT. 27
HS-027 515

EXPERIMENTAL INVESTIGATION OF THE INSTANTANEOUS HEAT TRANSFER IN THE CYLINDER OF A HIGH SPEED DIESEL ENGINE
HS-027 431

HEAT TRANSFER IN THE INDIRECT DIESEL ENGINE
HS-027 430

INVESTIGATIONS OF ENGINE COMPONENTS BY MEANS OF PHOTOELASTICITY
HS-027 435

STRENGTH ANALYSIS OF THERMALLY LOADED ENGINE COMPONENTS BY TWO-DIMENSIONAL AND THREE-DIMENSIONAL FINITE ELEMENT MODELS
HS-027 425

THE 80S. STANDARDS FORCE MOVE TO ELECTRONIC ENGINE CONTROLS
HS-027 437

TROUBLESHOOTING LACK OF ENGINE POWER
HS-028 553

ENGINEERING

ENGINE TECHNOLOGY FOR THE 1980'S. ENGINEERING KNOW-HOW IN ENGINE DESIGN, PT. 27
HS-027 515

ENGINEERS

IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

PERFORMING SAE (SOCIETY OF AUTOMOTIVE ENGINEERS) J551D RADIO INTERFERENCE TESTING OF AUTOMOTIVE VEHICLES USING THE PROGRAMMED AUTOMATIC SPECTRUM ANALYZER
HS-027 468

ENGINES

ASSESSMENT OF THE STATE OF TECHNOLOGY OF AUTOMOTIVE STIRLING ENGINES
HS-028 536

DESIGN AND FATIGUE LIFE EVALUATION OF PISTONS FOR HIGH BMEP (BRAKE MEAN EFFECTIVE PRESSURE) DIESEL ENGINES
HS-027 433

EFFECTS OF MICROWAVES ON THE PERFORMANCE OF INTERNAL COMBUSTION ENGINES. FINAL TECHNICAL REPORT
HS-028 527

MULTIPROCESSOR SYSTEM FOR DEVELOPING CONTROL STRATEGIES OF CAR ENGINES
HS-027 469

PREDICTION OF THERMAL LOADING OF SUPERCHARGED DIESEL ENGINES
HS-027 426

RESULTS OF MATCHING CALCULATIONS FOR TURBOCHARGED AND COMPOUND ENGINES WITH REDUCED HEAT LOSS
HS-027 428

STIRLING ENGINES FOR AUTOMOBILES
HS-028 386

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

ENGLAND

M6 RECONSTRUCTION 1976: TWO-WAY TRAFFIC USING NARROW LANES (STAFFORDSHIRE, ENGLAND)
HS-027 488

ENVIRONMENT

HIGH QUANTITY, LOW COST, HIGH ENVIRONMENT AUTOMOTIVE TRANSDUCERS, A NEW BREED FOR USE IN ADVANCED AUTOMOTIVE ELECTRONIC SYSTEMS
HS-027 461

ENVIRONMENTAL

POLICY CONFLICT--ENERGY, ENVIRONMENTAL, AND MATERIALS: AUTOMOTIVE FUEL-ECONOMY STANDARDS' IMPLICATIONS FOR MATERIALS. REPORT TO THE CONGRESS OF THE UNITED STATES
HS-028 516

EPIDEMIC

MOTORCYCLE ACCIDENTS IN TEENAGE MALES. A MODERN EPIDEMIC
HS-028 530

EQUATION

AN APPLICATION OF EQUATION ERROR IDENTIFICATION TECHNIQUES TO THE PROBLEM OF VEHICULAR DRAG PARAMETER DETERMINATION
HS-027 466

EQUIPMENT

A STRUCTURAL SURVEY OF CLASSES OF VEHICLES (RAIL EQUIPMENT) FOR CRASHWORTHINESS. FINAL REPORT
HS-027 419

SELECTING EQUIPMENT FOR FAILURE ANALYSIS
HS-027 513

ERROR

AN APPLICATION OF EQUATION ERROR IDENTIFICATION TECHNIQUES TO THE PROBLEM OF VEHICULAR DRAG PARAMETER DETERMINATION
HS-027 466

ESTIMATES

SURVEY AND ANALYSIS OF ENERGY INTENSITY ESTIMATES FOR URBAN TRANSPORTATION MODES
HS-028 512

EVALUATION

DESIGN AND FATIGUE LIFE EVALUATION OF PISTONS FOR HIGH BMEP (BRAKE MEAN EFFECTIVE PRESSURE) DIESEL ENGINES
HS-027 433

DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION
HS-027 432

DRIVER EDUCATION EVALUATION TESTS. SUMMARY REPORT
HS-028 380

ENERGY POLICY IMPACT EVALUATION
HS-028 510

EVALUATION OF SAFETY SYMBOLS
HS-027 414

MEASURES OF EFFECTIVENESS FOR MULTIMODAL URBAN TRAFFIC MANAGEMENT. VOL. 2: DEVELOPMENT AND EVALUATION OF TSM (TRANSPORTATION SYSTEMS MANAGEMENT) STRATEGIES. FINAL REPORT
HS-028 538

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

THE IMPACT OF FLYWHEEL-TRANSMISSIONS ON AUTOMOBILE PERFORMANCE: A LOGICAL BASIS FOR EVALUATION
HS-028 549

VEHICLE KILOMETERS TRAVELED: EVALUATION OF EXISTING DATA SOURCES
HS-028 514

55 MPH IMPACT PROGRAM EVALUATION. PHASE 1 SUMMARY REPORT
HS-805 213

EXPENDITURE

BEARING LIFE EXPENDITURE DURING RUNNING-IN
HS-027 512

EXPERIMENT

SOME DIESEL PISTON FEATURES IN DESIGN ANALYSIS AND EXPERIMENT
HS-027 434

EXPERIMENTAL

EXPERIMENTAL INVESTIGATION OF THE INSTANTANEOUS HEAT TRANSFER IN THE CYLINDER OF A HIGH SPEED DIESEL ENGINE
HS-027 431

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

EXPLORATORY

AN EXPLORATORY STUDY OF ATTITUDES AND OBSERVATIONS ON CHILD PROTECTION IN MOTOR VEHICLES
HS-027 480

EXPLOSION

EXPLOSION OF AUTOMOBILE BATTERIES AS A CAUSE OF OCULAR TRAUMA
HS-027 417

EXTERNAL

BLOOD ALCOHOL LEVEL DISCRIMINATION BY ALCOHOLICS: THE ROLE OF INTERNAL AND EXTERNAL CUES
HS-027 477

EYE
DRIVER EYE HEIGHT: A FIELD STUDY
HS-027 492

FAILURE
POST-PROCESSING GRAPHICS FOR BRITTLE FAILURE ANALYSIS
HS-027 514

SELECTING EQUIPMENT FOR FAILURE ANALYSIS
HS-027 513

FATAL
HIGH CERVICAL SPINE AND CRANIOCERVICAL JUNCTION INJURIES IN FATAL TRAFFIC ACCIDENTS: A RADIOLOGICAL STUDY
HS-027 479

FATALITIES
A SURVEY OF RHODE ISLAND MOTORCYCLE FATALITIES DURING 1975-1976
HS-027 445

FATIGUE
A UNIFIED PREDICTIVE TECHNIQUE FOR THE FATIGUE RESISTANCE OF CAST FERROUS-BASED METALS AND HIGH HARDNESS WROUGHT STEELS
HS-027 511

DESIGN AND FATIGUE LIFE EVALUATION OF PISTONS FOR HIGH BMEP (BRAKE MEAN EFFECTIVE PRESSURE) DIESEL ENGINES
HS-027 433

FATIGUE CRACK INITIATION AND GROWTH ANALYSIS FOR STRUCTURES
HS-027 508

FATIGUE RESISTANCE TESTING AND FORECASTING
HS-027 507

LONG LIFE RANDOM FATIGUE BEHAVIOR OF NOTCHED SPECIMENS IN SERVICE, IN SERVICE DUPLICATION TESTS, AND IN PROGRAM TESTS
HS-028 393

SOME CONSIDERATIONS IN USING STRAIN-LIFE APPROACH IN FATIGUE DESIGN
HS-027 510

FEDERAL
SALE OF USED MOTOR VEHICLES. FINAL STAFF REPORT TO THE FEDERAL TRADE COMMISSION AND PROPOSED TRADE REGULATION RULE (16 CFR PART 455)
HS-027 501

FERROUS
A UNIFIED PREDICTIVE TECHNIQUE FOR THE FATIGUE RESISTANCE OF CAST FERROUS-BASED METALS AND HIGH HARDNESS WROUGHT STEELS
HS-027 511

FIELD
DRIVER EYE HEIGHT: A FIELD STUDY
HS-027 492

FIGHT
THE GREAT ARKANSAS MOTORCYCLE HELMET LAW FIGHT
HS-027 476

FINITE
STRENGTH ANALYSIS OF THERMALLY LOADED ENGINE COMPONENTS BY TWO-DIMENSIONAL AND THREE-DIMENSIONAL FINITE ELEMENT MODELS
HS-027 425

FISCAL
U.S. DEPARTMENT OF TRANSPORTATION ANNUAL REPORT (NO. 12), FISCAL YEAR 1978
HS-028 542

FLEET
REMARKS BEFORE THE NATIONAL ASSOCIATION OF FLEET ADMINISTRATORS, NEW ORLEANS, MARCH 10, 1980
HS-810 368

FLOW
DELAYS AT PRIORITY INTERSECTIONS UNDER NON-STATIONARY TRAFFIC FLOW CONDITIONS
HS-028 506

FLYWHEEL
THE IMPACT OF FLYWHEEL-TRANSMISSIONS ON AUTOMOBILE PERFORMANCE: A LOGICAL BASIS FOR EVALUATION
HS-028 549

FORCE
THE 80S. STANDARDS FORCE MOVE TO ELECTRONIC ENGINE CONTROLS
HS-027 437

FORCES
EFFECT OF WHEEL SUSPENSION TYPES ON WHEEL LOAD AND SIDE FORCES (EINFLUSS DER RADAUFHANGUNG AUF RADLASTEN UND SEITENKRAFTE)
HS-028 509

OCCUPANT-VS-AIRBAG FORCES MEASURED
HS-027 504

FORD
FORD/DOE (DEPARTMENT OF ENERGY) SODIUM-SULFUR BATTERY ELECTRIC VEHICLE DEVELOPMENT. PHASE 1-A. FINAL REPORT
HS-028 529

FORECASTING
AN APPRAISAL OF AGGREGATE AND DISAGGREGATE CAR OWNERSHIP FORECASTING METHODS
HS-028 518

FATIGUE RESISTANCE TESTING AND FORECASTING
HS-027 507

FOREIGN
FOREIGN OIL DEPENDENCE: STATE-LEVEL ANALYSIS (NEW YORK)
HS-028 513

IGNITION NOISE OF FOREIGN AND DOMESTIC VEHICLES IN USE IN THE UNITED STATES
HS-027 467

PROPOSED AMENDMENTS TO TITLE V OF THE MOTOR VEHICLE INFORMATION AND COST SAVINGS ACT. STATEMENT BEFORE THE SUBCOMMITTEE ON ENERGY AND POWER, HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE, MARCH 28, 1980
HS-810 370

FREEWAY
FREEWAY TRAFFIC MANAGEMENT. FINAL REPORT
HS-027 473

FRONT
TYRE (TIRE) FACTORS AND FRONT WHEEL VIBRATIONS
HS-028 543

FUEL
CALCULATION OF FUEL CONSUMPTION DUE TO TRAFFIC CONGESTION IN A CASE-STUDY METROPOLITAN AREA
HS-028 505

CONSUMERS' RESPONSES TO FUEL-EFFICIENT VEHICLES: A CRITICAL REVIEW OF ECONOMETRIC STUDIES
HS-027 438

FINAL REGULATORY ANALYSIS OF THE MODEL YEAR 1982 LIGHT TRUCK FUEL ECONOMY STANDARDS
HS-805 291

METHODS OF EVALUATING THE EFFECT OF AERODYNAMICS ON THE FUEL CONSUMPTION OF COMMERCIAL VEHICLES
HS-027 487

POLICY CONFLICT--ENERGY, ENVIRONMENTAL, AND MATERIALS: AUTOMOTIVE FUEL-ECONOMY STANDARDS' IMPLICATIONS FOR MATERIALS. REPORT TO THE CONGRESS OF THE UNITED STATES
HS-028 516

SURVEY OF LIQUID HYDROGEN CONTAINER TECHNIQUES FOR HIGHWAY VEHICLE FUEL SYSTEM APPLICATIONS
HS-028 550

THE FUEL-SAVING SHAPE OF CARS TO COME
HS-027 497

VEHICLE FUEL ECONOMY REVIEW
HS-027 499

FUELS
AUTOMOTIVE FUELS FOR THE 1980'S
HS-027 519

FUN
LEARNING IS FUN WITH THE NATIONAL SAFETY COUNCIL'S CHILD SAFETY CLUB
HS-027 475

FUNKTION
ELECTRONIC DIGITAL ANTI-LOCKING SYSTEM FOR PASSENGER CARS, ITS DESIGN AND OPERATION (ANTIBLOCKIERSYSTEM FUR PERSONENWAGEN MIT DIGITALER ELEKTRONIK--AUFBAU UND FUNKTION)
HS-028 519

GASOHOL
GASOHOL CONSUMPTION SKYROCKETS. TRY A LITTLE "WHITE LIGHTNING" IN YOUR TANK
HS-027 436

GASOHOL. A TECHNICAL MEMORANDUM
HS-027 482

GASOLINE
AN INVESTIGATION OF THE VARIABILITY OF GASOLINE CONSUMPTION AMONG STATES
HS-027 440

GAUGE
VACUUM GAUGE: A TOP-NOTCH TROUBLESHOOTER
HS-028 533

GEAR
DIAGNOSTICS OF GEAR ASSEMBLY--A NEW APPROACH USING IMPACT ANALYSIS
HS-028 395

GENEVA
VEHICLE SAFETY IN THE WORLD CAR MARKETPLACE. REMARKS BEFORE THE WORLD MOTOR INDUSTRY CONFERENCE, GENEVA, SWITZERLAND, MARCH 3, 1980
HS-810 367

GOODS
HEAVY GOODS VEHICLE TAXATION IN THE UNITED KINGDOM
HS-028 526

GOVERNMENT
JAPANESE GOVERNMENT WHITE PAPER ON TRANSPORTATION SAFETY. 1979 ED.
HS-027 471

GOVERNOR
THE TRUCK ELECTRONIC GOVERNOR SYSTEM
HS-027 464

GRAPHICS
POST-PROCESSING GRAPHICS FOR BRITTLE FAILURE ANALYSIS
HS-027 514

GROWTH
FATIGUE CRACK INITIATION AND GROWTH ANALYSIS FOR STRUCTURES
HS-027 508

GUIDE
A GUIDE TO REPORTING HIGHWAY STATISTICS
HS-027 448

PARATRANSIT RESOURCE GUIDE
HS-028 539

THE CAR BOOK: A CONSUMER'S GUIDE TO CAR BUYING
HS-805 580

GUIDEWAY
AUTOMATED CONTROL OF GUIDEWAY TRANSIT VEHICLES
HS-027 457

GUIDING
IS DELINEATION NEEDED? (ROADWAY TREATMENTS FOR GUIDING AND ADVISING MOTORISTS)
HS-028 535

HANDLING
AN ANALYTICAL STUDY OF ELECTRIC VEHICLE HANDLING DYNAMICS
HS-028 537

HAPPINESS
WILL THERE EVER BE HAPPINESS IN TIRE LAND?
HS-028 504

HARDNESS

A UNIFIED PREDICTIVE TECHNIQUE FOR THE FATIGUE RESISTANCE OF CAST FERROUS-BASED METALS AND HIGH HARDNESS WROUGHT STEELS
HS-027 511

HAZARD

ROAD ACCIDENTS: ARE DRUGS OTHER THAN ALCOHOL A HAZARD?
HS-027 444

HEAD

HEAD ON. PAINTED IN SAFETY (MOTORCYCLE VISIBILITY)
HS-028 552

HEADLAMP

"TOWN BEAMS" FOR VEHICLES--EXPERIENCE WITH AN AUTOMATIC HEADLAMP DIMMING SYSTEM
HS-027 490

HEADWAY

AN ACCIDENT-SEVERITY ANALYSIS FOR A UNIFORM-SPACING HEADWAY POLICY
HS-027 463

HEARING

THE EFFECT OF HEARING PROTECTORS ON THE PERCEPTION OF WARNING AND INDICATOR SOUNDS--A GENERAL REVIEW
HS-028 394

HEAT

ADVANCED APPROACHES FOR HEAT TRANSFER CALCULATIONS
HS-027 429

DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION
HS-027 432

EFFECT OF PARTIAL SUPPRESSION OF HEAT LOSS TO COOLANT ON THE HIGH OUTPUT DIESEL ENGINE CYCLE
HS-027 427

EXPERIMENTAL INVESTIGATION OF THE INSTANTANEOUS HEAT TRANSFER IN THE CYLINDER OF A HIGH SPEED DIESEL ENGINE
HS-027 431

HEAT TRANSFER IN THE INDIRECT DIESEL ENGINE
HS-027 430

RESULTS OF MATCHING CALCULATIONS FOR TURBOCHARGED AND COMPOUND ENGINES WITH REDUCED HEAT LOSS
HS-027 428

HEAVY

HEAVY GOODS VEHICLE TAXATION IN THE UNITED KINGDOM
HS-028 526

HEIGHT

DRIVER EYE HEIGHT: A FIELD STUDY
HS-027 492

HEIGHTS

IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

HELMET

IMPACT OF HELMET LAW REPEAL. REPORTS GIVEN ON DOT (DEPARTMENT OF TRANSPORTATION) 4-STATE MOTORCYCLE HELMET STUDY
HS-027 451

IMPACT OF MOTORCYCLE HELMET LAW REPEAL
HS-027 481

THE GREAT ARKANSAS MOTORCYCLE HELMET LAW FIGHT
HS-027 476

HIGHWAY

A GUIDE TO REPORTING HIGHWAY STATISTICS
HS-027 448

ACTS ADMINISTERED BY THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION. REV. ED., MARCH 1980
HS-805 294

ALCOHOL & HIGHWAY SAFETY LAWS: A NATIONAL OVERVIEW
HS-805 173

AUTOMATIC LONGITUDINAL CONTROL OF HIGHWAY VEHICLES
HS-027 455

CALIFORNIA'S SAFETY EFFORTS--PAST AND PRESENT (HIGHWAY CONSTRUCTION AND MAINTENANCE ZONES)
HS-027 493

COMMERCIAL VEHICLE MAINTENANCE AND SAFETY INSPECTION PROGRAMS. A REPORT TO THE SECRETARY OF TRANSPORTATION BY THE NATIONAL HIGHWAY SAFETY ADVISORY COMMITTEE
HS-804 789

DEVELOPMENT OF A WET WEATHER SAFETY INDEX. FINAL REPORT (HIGHWAY ACCIDENT PREDICTION AND REDUCTION)
HS-027 491

EFFECTS OF SEATBELT LEGISLATION AND REDUCTION OF HIGHWAY SPEED LIMITS IN ONTARIO
HS-027 449

ENERGY CONSERVATION POTENTIAL OF OFF-HIGHWAY RECREATIONAL MOTOR VEHICLE. REPORT TO THE CONGRESS
HS-028 392

HIGHWAY ACCIDENT REPORT. MULTIPLE-VEHICLE COLLISION IN A CONSTRUCTION ZONE, U.S. INTERSTATE 80, NEAR LARAMIE, WYOMING, AUGUST 22, 1979
HS-028 540

HIGHWAY LIABILITY--A REVIEW OF WORKZONE ACCIDENT CASES
HS-027 495

HIGHWAY SAFETY DATA. A REPORT TO THE SECRETARY OF TRANSPORTATION BY THE NATIONAL HIGHWAY SAFETY ADVISORY COMMITTEE
HS-804 788

SURVEY OF LIQUID HYDROGEN CONTAINER TECHNIQUES FOR HIGHWAY VEHICLE FUEL SYSTEM APPLICATIONS
HS-028 550

TESTING A PROTOTYPE INDUCTIVE POWER COUPLING FOR AN ELECTRIC HIGHWAY SYSTEM
HS-027 456

HIGHWAYS

MANUAL ON UNIFORM TRAFFIC CONTROL DEVICES FOR STREETS AND HIGHWAYS. 1978 ED.
HS-025 657

HOUSE

PROPOSED AMENDMENTS TO TITLE V OF THE MOTOR VEHICLE INFORMATION AND COST SAVINGS ACT. STATEMENT BEFORE THE SUBCOMMITTEE ON ENERGY AND POWER, HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE, MARCH 28, 1980
HS-810 370

HWY

A REVIEW OF NHTSA'S (NATIONAL HWY. TRAFFIC SAFFETY ADMINISTRATION) VEHICLE COMPLIANCE TESTING POLICIES AND PROCEDURES
HS-028 397

HYDROGEN

SURVEY OF LIQUID HYDROGEN CONTAINER TECHNIQUES FOR HIGHWAY VEHICLE FUEL SYSTEM APPLICATIONS
HS-028 550

IDENTIFICATION

A RAPID, SYSTEMATIC, AND COMPREHENSIVE CLASSIFICATION SYSTEM FOR THE IDENTIFICATION AND COMPARISON OF MOTOR VEHICLE PAINT SAMPLES. 1: THE NATURE AND SCOPE OF THE CLASSIFICATION SYSTEM
HS-027 439

AN APPLICATION OF EQUATION ERROR IDENTIFICATION TECHNIQUES TO THE PROBLEM OF VEHICULAR DRAG PARAMETER DETERMINATION
HS-027 466

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 1. FINAL SUMMARY REPORT
HS-805 270

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 2. FINAL TECHNICAL REPORT
HS-805 271

IDENTIFICATION OF SUPERIOR ENERGY-ABSORBING MATERIALS FOR SCHOOL BUS INTERIORS. VOLUME 3. APPENDICES. FINAL REPORT
HS-805 272

MICROWAVE AUTOMATIC VEHICLE IDENTIFICATION (AVI) SYSTEM
HS-027 459

IEEE

IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

IGNITION

IGNITION NOISE OF FOREIGN AND DOMESTIC VEHICLES IN USE IN THE UNITED STATES
HS-027 467

ILLINOIS

IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

IMPACT

APPROACH TO ASSESSING THE IMPACT OF ENERGY CONSERVATION POLICIES ON TRANSPORTATION DEMAND

SURVEY
A STRUCTURAL SURVEY OF CLASSES OF VEHICLES (RAIL EQUIPMENT) FOR CRASHWORTHINESS. FINAL REPORT
HS-027 419

A SURVEY OF RHODE ISLAND MOTORCYCLE FATALITIES DURING 1975-1976
HS-027 445

SURVEY AND ANALYSIS OF ENERGY INTENSITY ESTIMATES FOR URBAN TRANSPORTATION MODES
HS-028 512

SURVEY OF LIQUID HYDROGEN CONTAINER TECHNIQUES FOR HIGHWAY VEHICLE FUEL SYSTEM APPLICATIONS
HS-028 550

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

VEHICLE STRUCTURAL ANALYSIS: A SURVEY
HS-028 547

SURVEYS
THE U.S. DEPARTMENT OF TRANSPORTATION SURVEYS ON SAFETY BELT USE AND THEIR COMFORT AND CONVENIENCE. FACT SHEET
HS-805 307

SURVIVE
CONSPICUITY. HOW TO SURVIVE THE "I DIDN'T SEE HIM" SYNDROME (MOTORCYCLIST VISIBILITY)
HS-027 498

SUSPENSION
EFFECT OF WHEEL SUSPENSION TYPES ON WHEEL LOAD AND SIDE FORCES (EINFLUSS DER RADAUFHANGUNG AUF RADLASTEN UND SEITENKRAFTE)
HS-028 509

THE URBAN CAR AND ITS POWER TRANSMISSION AND SUSPENSION SYSTEMS
HS-028 522

SWITZERLAND
VEHICLE SAFETY IN THE WORLD CAR MARKETPLACE. REMARKS BEFORE THE WORLD MOTOR INDUSTRY CONFERENCE, GENEVA, SWITZERLAND, MARCH 3, 1980
HS-810 367

SYMBOLS
EVALUATION OF SAFETY SYMBOLS
HS-027 414

SYNDROME
CONSPICUITY. HOW TO SURVIVE THE "I DIDN'T SEE HIM" SYNDROME (MOTORCYCLIST VISIBILITY)
HS-027 498

SYSTEMATIC
A RAPID, SYSTEMATIC, AND COMPREHENSIVE CLASSIFICATION SYSTEM FOR THE IDENTIFICATION AND COMPARISON OF MOTOR VEHICLE PAINT SAMPLES. 1: THE NATURE AND SCOPE OF THE CLASSIFICATION SYSTEM
HS-027 439

TAILGATE
COMPUTER AIDS LIGHTWEIGHT COMPONENT DESIGN (APPLICATION TO AN AUTOMOBILE TAILGATE)
HS-027 505

TANK
GASOHOL CONSUMPTION SKYROCKETS. TRY A LITTLE "WHITE LIGHTNING" IN YOUR TANK
HS-027 436

TAXATION
HEAVY GOODS VEHICLE TAXATION IN THE UNITED KINGDOM
HS-028 526

TECHNOLOGY
ASSESSMENT OF THE STATE OF TECHNOLOGY OF AUTOMOTIVE STIRLING ENGINES
HS-028 536

ENGINE TECHNOLOGY FOR THE 1980'S. ENGINEERING KNOW-HOW IN ENGINE DESIGN, PT. 27
HS-027 515

IEEE (INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INC.) VEHICULAR TECHNOLOGY CONFERENCE (29TH ANNUAL) RECORD OF PAPERS PRESENTED, ARLINGTON HEIGHTS, ILLINOIS, MARCH 27-30, 1979
HS-027 452

TEENAGE
MOTORCYCLE ACCIDENTS IN TEENAGE MALES. A MODERN EPIDEMIC
HS-028 530

TELEPHONE
HIGH CAPACITY AUTOMOBILE TELEPHONE SYSTEM
HS-027 462

TEMPERATURE
DETERMINATION OF LOCAL HEAT TRANSFER COEFFICIENTS AT THE PISTON OF A HIGH SPEED DIESEL ENGINE BY EVALUATION OF MEASURED TEMPERATURE DISTRIBUTION
HS-027 432

TENNESSEE

THE USE OF CHILD PASSENGER SAFETY DEVICES IN TENNESSEE
HS-027 474

TESTING

A REVIEW OF NHTSA'S (NATIONAL HWY. TRAFFIC SAFFETY ADMINISTRATION) VEHICLE COMPLIANCE TESTING POLICIES AND PROCEDURES
HS-028 397

FATIGUE RESISTANCE TESTING AND FORECASTING
HS-027 507

PERFORMING SAE (SOCIETY OF AUTOMOTIVE ENGINEERS) J551D RADIO INTERFERENCE TESTING OF AUTOMOTIVE VEHICLES USING THE PROGRAMMED AUTOMATIC SPECTRUM ANALYZER
HS-027 468

TESTING A PROTOTYPE INDUCTIVE POWER COUPLING FOR AN ELECTRIC HIGHWAY SYSTEM
HS-027 456

TESTS

DRIVER EDUCATION EVALUATION TESTS. SUMMARY REPORT
HS-028 380

LONG LIFE RANDOM FATIGUE BEHAVIOR OF NOTCHED SPECIMENS IN SERVICE, IN SERVICE DUPLICATION TESTS, AND IN PROGRAM TESTS
HS-028 393

MICROPROCESSOR-BASED SYSTEM FOR ROLL-DOWN AND ACCELERATION TESTS
HS-027 460

THEORETICAL

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

THERMAL

DIESEL ENGINE THERMAL LOADING
HS-027 423

PREDICTION OF THERMAL LOADING OF SUPERCHARGED DIESEL ENGINES
HS-027 426

SURVEY OF THEORETICAL AND EXPERIMENTAL EVALUATION OF THERMAL LOADING OF DIESEL ENGINES IN NORWAY
HS-027 424

15 KWE (NOMINAL) SOLAR THERMAL ELECTRIC POWER CONVERSION CONCEPT DEFINITION STUDY--STEAM RANKINE TURBINE SYSTEM. FINAL REPORT
HS-027 483

15 KWE (NOMINAL) SOLAR THERMAL-ELECTRIC POWER CONVERSION CONCEPT DEFINITION STUDY--STEAM RANKINE RECIPROCATOR SYSTEM. FINAL REPORT
HS-027 484

THERMALLY

STRENGTH ANALYSIS OF THERMALLY LOADED ENGINE COMPONENTS BY TWO-DIMENSIONAL AND THREE-DIMENSIONAL FINITE ELEMENT MODELS
HS-027 425

THROMBOSIS

SEAT BELT AORTA: ACUTE DISSECTION AND THROMBOSIS OF THE ABDOMINAL AORTA
HS-028 502

TIRE

LEGAL BUT LETHAL (BRITISH TIRE LAWS)
HS-027 420

TYRE (TIRE) FACTORS AND FRONT WHEEL VIBRATIONS
HS-028 543

WILL THERE EVER BE HAPPINESS IN TIRE LAND?
HS-028 504

TITLE

PROPOSED AMENDMENTS TO TITLE V OF THE MOTOR VEHICLE INFORMATION AND COST SAVINGS ACT. STATEMENT BEFORE THE SUBCOMMITTEE ON ENERGY AND POWER, HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE, MARCH 28, 1980
HS-810 370
